Celery is a simple, flexible, and reliable distributed system to process vast amounts of messages, while providing operations with the tools required to maintain such a system.

It's a task queue with focus on real-time processing, while also supporting task scheduling.

Celery has a large and diverse community of users and contributors, you should come join us on IRC or our mailing-list.

Celery is Open Source and licensed under the BSD License.
This project relies on your generous donations.

If you are using Celery to create a commercial product, please consider becoming our backer or our sponsor to ensure Celery’s future.
Getting Started

• If you’re new to Celery you can get started by following the *First Steps with Celery* tutorial.
• You can also check out the *FAQ*.

3.2 Getting Started

**Release** 4.4

**Date** Dec 16, 2019

3.2.1 Introduction to Celery
What's a Task Queue?

Task queues are used as a mechanism to distribute work across threads or machines. A task queue’s input is a unit of work called a task. Dedicated worker processes constantly monitor task queues for new work to perform.

Celery communicates via messages, usually using a broker to mediate between clients and workers. To initiate a task the client adds a message to the queue, the broker then delivers that message to a worker.

A Celery system can consist of multiple workers and brokers, giving way to high availability and horizontal scaling. Celery is written in Python, but the protocol can be implemented in any language. In addition to Python there’s node-celery and node-celery-ts for Node.js, and a PHP client.

Language interoperability can also be achieved exposing an HTTP endpoint and having a task that requests it (webhooks).

What do I need?

### Version Requirements

Celery version 4.0 runs on

- Python 2.7, 3.4, 3.5
- PyPy 5.4, 5.5

This is the last version to support Python 2.7, and from the next version (Celery 5.x) Python 3.5 or newer is required.

If you’re running an older version of Python, you need to be running an older version of Celery:

- Python 2.6: Celery series 3.1 or earlier.
- Python 2.5: Celery series 3.0 or earlier.
- Python 2.4 was Celery series 2.2 or earlier.

Celery is a project with minimal funding, so we don’t support Microsoft Windows. Please don’t open any issues related to that platform.
Celery requires a message transport to send and receive messages. The RabbitMQ and Redis broker transports are feature complete, but there’s also support for a myriad of other experimental solutions, including using SQLite for local development.

Celery can run on a single machine, on multiple machines, or even across data centers.

**Get Started**

If this is the first time you’re trying to use Celery, or if you haven’t kept up with development in the 3.1 version and are coming from previous versions, then you should read our getting started tutorials:

- *First Steps with Celery*
- *Next Steps*

**Celery is…**

**Simple**

Celery is easy to use and maintain, and it *doesn’t need configuration files.*

It has an active, friendly community you can talk to for support, including a mailing-list and an **IRC channel.**

Here’s one of the simplest applications you can make:

```python
from celery import Celery

app = Celery('hello', broker='amqp://guest@localhost//')

@app.task
def hello():
    return 'hello world'
```

**Highly Available**

Workers and clients will automatically retry in the event of connection loss or failure, and some brokers support HA in way of **Primary/Primary** or **Primary/Replica** replication.

**Fast**

A single Celery process can process millions of tasks a minute, with sub-millisecond round-trip latency (using RabbitMQ, librabbitmq, and optimized settings).

**Flexible**

Almost every part of Celery can be extended or used on its own, Custom pool implementations, serializers, compression schemes, logging, schedulers, consumers, producers, broker transports, and much more.

**It supports**

- **Brokers**
  - RabbitMQ, Redis,
  - Amazon SQS, and more…
• Concurrency
  • prefork (multiprocessing),
  • Eventlet, gevent
  • thread (multithreaded)
  • solo (single threaded)
• Result Stores
  • AMQP, Redis
  • Memcached,
  • SQLAlchemy, Django ORM
  • Apache Cassandra, Elasticsearch, Riak
  • MongoDB, CouchDB, Couchbase, ArangoDB
  • Amazon DynamoDB, Amazon S3
  • Microsoft Azure Block Blob, Microsoft Azure Cosmos DB
  • File system
• Serialization
  • pickle, json, yaml, msgpack.
  • zlib, bzip2 compression.
  • Cryptographic message signing.

Features

• Monitoring
  A stream of monitoring events is emitted by workers and is used by built-in and external tools to tell you what your cluster is doing – in real-time.

  Read more...

• Work-flows
  Simple and complex work-flows can be composed using a set of powerful primitives we call the “canvas”, including grouping, chaining, chunking, and more.

  Read more...

• Time & Rate Limits
  You can control how many tasks can be executed per second/minute/hour, or how long a task can be allowed to run, and this can be set as a default, for a specific worker or individually for each task type.

  Read more...

• Scheduling
  You can specify the time to run a task in seconds or a datetime, or you can use periodic tasks for recurring events based on a simple interval, or Crontab expressions supporting minute, hour, day of week, day of month, and month of year.

  Read more...

• Resource Leak Protection
  The --max-tasks-per-child option is used for user tasks leaking resources, like memory or file descriptors, that are simply out of your control.

  Read more...

• User Components
  Each worker component can be customized, and additional components can be defined by the user. The worker is built up using “bootsteps” — a dependency graph enabling fine grained control of the worker’s internals.
Framework Integration

Celery is easy to integrate with web frameworks, some of them even have integration packages:

<table>
<thead>
<tr>
<th>Framework</th>
<th>Integration Package</th>
</tr>
</thead>
<tbody>
<tr>
<td>Pyramid</td>
<td>pyramid_celery</td>
</tr>
<tr>
<td>Pylons</td>
<td>celery-pylons</td>
</tr>
<tr>
<td>Flask</td>
<td>not needed</td>
</tr>
<tr>
<td>web2py</td>
<td>web2py-celery</td>
</tr>
<tr>
<td>Tornado</td>
<td>tornado-celery</td>
</tr>
<tr>
<td>Tryton</td>
<td>celery_tryton</td>
</tr>
</tbody>
</table>

For Django see First steps with Django.

The integration packages aren’t strictly necessary, but they can make development easier, and sometimes they add important hooks like closing database connections at `fork(2)`.

Quick Jump

I want to

- get the return value of a task
- use logging from my task
- learn about best practices
- create a custom task base class
- add a callback to a group of tasks
- split a task into several chunks
- optimize the worker
- see a list of built-in task states
- create custom task states
- set a custom task name
- track when a task starts
- retry a task when it fails
- get the id of the current task
- know what queue a task was delivered to
- see a list of running workers
- purge all messages
- inspect what the workers are doing
- see what tasks a worker has registered
- migrate tasks to a new broker
- see a list of event message types
- contribute to Celery
- learn about available configuration settings
- get a list of people and companies using Celery
- write my own remote control command
- change worker queues at runtime

- Applications

3.2. Getting Started
Installation

You can install Celery either via the Python Package Index (PyPI) or from source.

To install using `pip`:

```bash
$ pip install -U Celery
```

Bundles

Celery also defines a group of bundles that can be used to install Celery and the dependencies for a given feature.

You can specify these in your requirements or on the `pip` command-line by using brackets. Multiple bundles can be specified by separating them by commas.

```bash
$ pip install "celery[librabbitmq]"
$ pip install "celery[librabbitmq,redis,auth,msgpack]"
```

The following bundles are available:

Serializers

- `celery[auth]` for using the `auth` security serializer.
- `celery[msgpack]` for using the msgpack serializer.
- `celery[yaml]` for using the yaml serializer.

Concurrency

- `celery[eventlet]` for using the `eventlet` pool.
- `celery[gevent]` for using the `gevent` pool.
Transports and Backends

- `celery[librabbitmq]` for using the librabbitmq C library.
- `celery[redis]` for using Redis as a message transport or as a result backend.
- `celery[sqs]` for using Amazon SQS as a message transport (experimental).
- `celery[tbllib]` for using the `task_remote_tracebacks` feature.
- `celery[memcache]` for using Memcached as a result backend (using `pylibmc`).
- `celery[pymemcache]` for using Memcached as a result backend (pure-Python implementation).
- `celery[cassandra]` for using Apache Cassandra as a result backend with DataStax driver.
- `celery[couchbase]` for using Couchbase as a result backend.
- `celery[arangodb]` for using ArangoDB as a result backend.
- `celery[elasticsearch]` for using Elasticsearch as a result backend.
- `celery[riak]` for using Riak as a result backend.
- `celery[dynamodb]` for using AWS DynamoDB as a result backend.
- `celery[zoookeeper]` for using Zookeeper as a message transport.
- `celery[sqlalchemy]` for using SQLAlchemy as a result backend (supported).
- `celery[consul]` for using the Consul.io Key/Value store as a message transport or result backend (experimental).

`celery[django]` specifies the lowest version possible for Django support.

You should probably not use this in your requirements, it’s here for informational purposes only.

Downloading and installing from source

Download the latest version of Celery from PyPI:

https://pypi.org/project/celery/

You can install it by doing the following:

```bash
$ tar xvfz celery-0.0.0.tar.gz
$ cd celery-0.0.0
$ python setup.py build
# python setup.py install
```

The last command must be executed as a privileged user if you aren’t currently using a virtualenv.

Using the development version

With pip

The Celery development version also requires the development versions of `kombu`, `amqp`, `billiard`, and `vine`.

3.2. Getting Started
You can install the latest snapshot of these using the following pip commands:

$$
pip install https://github.com/celery/celery/zipball/master#egg=celery  
pip install https://github.com/celery/billiard/zipball/master#egg=billiard  
pip install https://github.com/celery/py-amqp/zipball/master#egg=amqp  
pip install https://github.com/celery/kombu/zipball/master#egg=kombu  
pip install https://github.com/celery/vine/zipball/master#egg=vine  
$$

With git

Please see the Contributing section.

### 3.2.2 Brokers

**Release 4.4**

**Date** Dec 16, 2019

Celery supports several message transport alternatives.

**Broker Instructions**

**Using RabbitMQ**

- **Installation & Configuration**
  - **Installing the RabbitMQ Server**
    - Setting up RabbitMQ
    - Installing RabbitMQ on macOS
      - Configuring the system host name
      - Starting/Stopping the RabbitMQ server

**Installation & Configuration**

RabbitMQ is the default broker so it doesn’t require any additional dependencies or initial configuration, other than the URL location of the broker instance you want to use:

```
broker_url = 'amqp://myuser:mypassword@localhost:5672/myvhost'
```

For a description of broker URLs and a full list of the various broker configuration options available to Celery, see Broker Settings, and see below for setting up the username, password and vhost.

**Installing the RabbitMQ Server**

See Installing RabbitMQ over at RabbitMQ’s website. For macOS see Installing RabbitMQ on macOS.
Note: If you’re getting `nodedown` errors after installing and using `rabbitmqctl` then this blog post can help you identify the source of the problem:

http://www.somic.org/2009/02/19/on-rabbitmqctl-and-badrpcnodedown/

Setting up RabbitMQ

To use Celery we need to create a RabbitMQ user, a virtual host and allow that user access to that virtual host:

```bash
$ sudo rabbitmqctl add_user myuser mypassword

$ sudo rabbitmqctl add_vhost myvhost

$ sudo rabbitmqctl set_user_tags myuser mytag

$ sudo rabbitmqctl set_permissions -p myvhost myuser ".*" ".*" ".*"
```

Substitute in appropriate values for `myuser`, `mypassword` and `myvhost` above.

See the RabbitMQ Admin Guide for more information about access control.

Installing RabbitMQ on macOS

The easiest way to install RabbitMQ on macOS is using Homebrew the new and shiny package management system for macOS.

First, install Homebrew using the one-line command provided by the Homebrew documentation:

```bash
ruby -e "$(curl -fsSL https://raw.githubusercontent.com/Homebrew/homebrew/go/install)"
```

Finally, we can install RabbitMQ using `brew`:

```bash
$ brew install rabbitmq
```

After you’ve installed RabbitMQ with `brew` you need to add the following to your path to be able to start and stop the broker: add it to the start-up file for your shell (e.g., `.bash_profile` or `.profile`).

```bash
PATH=$PATH:/usr/local/sbin
```

Configuring the system host name

If you’re using a DHCP server that’s giving you a random host name, you need to permanently configure the host name. This is because RabbitMQ uses the host name to communicate with nodes.

Use the `scutil` command to permanently set your host name:

```bash
$ sudo scutil --set HostName myhost.local
```

Then add that host name to `/etc/hosts` so it’s possible to resolve it back into an IP address:

3.2. Getting Started
If you start the `rabbitmq-server`, your rabbit node should now be `rabbit@myhost`, as verified by `rabbitmqctl`:

```
$ sudo rabbitmqctl status
Status of node rabbit@myhost ...
{running_applications, [{rabbit, "RabbitMQ", "1.7.1"},
                         {mnesia, "MNESIA CXC 138 12", "4.4.12"},
                         {os_mon, "CPO CXC 138 46", "2.2.4"},
                         {sasl, "SASL CXC 138 11", "2.1.8"},
                         {stdlib, "ERTS CXC 138 10", "1.16.4"},
                         {kernel, "ERTS CXC 138 10", "2.13.4"}]},
{nodes, [rabbit@myhost]},
{running_nodes, [rabbit@myhost]}},
...done.
```

This is especially important if your DHCP server gives you a host name starting with an IP address, (e.g., `23.10.112.31.comcast.net`). In this case RabbitMQ will try to use `rabbit@23`: an illegal host name.

### Starting/Stopping the RabbitMQ server

To start the server:

```
$ sudo rabbitmq-server
```

You can also run it in the background by adding the `-detached` option (note: only one dash):

```
$ sudo rabbitmq-server -detached
```

Never use `kill (kill(1))` to stop the RabbitMQ server, but rather use the `rabbitmqctl` command:

```
$ sudo rabbitmqctl stop
```

When the server is running, you can continue reading Setting up RabbitMQ.

### Using Redis

**Installation**

For the Redis support you have to install additional dependencies. You can install both Celery and these dependencies in one go using the `celery[redis]` bundle:

```
$ pip install -U "celery[redis]"
```

**Configuration**

Configuration is easy, just configure the location of your Redis database:

```
app.conf.broker_url = 'redis://localhost:6379/0'
```

Where the URL is in the format of:
redis://:password@hostname:port/db_number

all fields after the scheme are optional, and will default to localhost on port 6379, using database 0.

If a Unix socket connection should be used, the URL needs to be in the format:

redis+socket:///path/to/redis.sock

Specifying a different database number when using a Unix socket is possible by adding the virtual_host parameter to the URL:

redis+socket:///path/to/redis.sock?virtual_host=db_number

It is also easy to connect directly to a list of Redis Sentinel:

```python
app.conf.broker_transport_options = { 'master_name': "cluster1" }
```

Visibility Timeout

The visibility timeout defines the number of seconds to wait for the worker to acknowledge the task before the message is redelivered to another worker. Be sure to see Caveats below.

This option is set via the broker_transport_options setting:

```python
app.conf.broker_transport_options = { 'visibility_timeout': 3600 } # 1 hour.
```

The default visibility timeout for Redis is 1 hour.

Results

If you also want to store the state and return values of tasks in Redis, you should configure these settings:

```python
app.conf.result_backend = 'redis://localhost:6379/0'
```

For a complete list of options supported by the Redis result backend, see Redis backend settings.

If you are using Sentinel, you should specify the master_name using the result_backend_transport_options setting:

```python
app.conf.result_backend_transport_options = { 'master_name': "mymaster" }
```

Caveats

Fanout prefix

Broadcast messages will be seen by all virtual hosts by default.

You have to set a transport option to prefix the messages so that they will only be received by the active virtual host:

```python
app.conf.broker_transport_options = { 'fanout_prefix': True }
```
Note that you won’t be able to communicate with workers running older versions or workers that doesn’t have this setting enabled.
This setting will be the default in the future, so better to migrate sooner rather than later.

**Fanout patterns**

Workers will receive all task related events by default.
To avoid this you must set the `fanout_patterns` fan option so that the workers may only subscribe to worker related events:

```python
app.conf.broker_transport_options = {'fanout_patterns': True}
```

Note that this change is backward incompatible so all workers in the cluster must have this option enabled, or else they won’t be able to communicate.
This option will be enabled by default in the future.

**Visibility timeout**

If a task isn’t acknowledged within the *Visibility Timeout* the task will be redelivered to another worker and executed.
This causes problems with ETA/countdown/retry tasks where the time to execute exceeds the visibility timeout; in fact if that happens it will be executed again, and again in a loop.
So you have to increase the visibility timeout to match the time of the longest ETA you’re planning to use.
Note that Celery will redeliver messages at worker shutdown, so having a long visibility timeout will only delay the redelivery of ‘lost’ tasks in the event of a power failure or forcefully terminated workers.
Periodic tasks won’t be affected by the visibility timeout, as this is a concept separate from ETA/countdown.
You can increase this timeout by configuring a transport option with the same name:

```python
app.conf.broker_transport_options = {'visibility_timeout': 43200}
```

The value must be an int describing the number of seconds.

**Key eviction**

Redis may evict keys from the database in some situations
If you experience an error like:

```python
InconsistencyError: Probably the key ('_kombu.binding.celery') has been removed from the Redis database.
```

then you may want to configure the `redis-server` to not evict keys by setting the `timeout` parameter to 0 in the redis configuration file.

**Using Amazon SQS**
### Installation

For the Amazon SQS support you have to install additional dependencies. You can install both Celery and these dependencies in one go using the `celery[sqs]` bundle:

```bash
$ pip install celery[sqs]
```

### Configuration

You have to specify SQS in the broker URL:

```python
broker_url = 'sqs://ABCDEFGHIJKLMNOPQRST:ZYXK7NiynGlTogH8Nj+P9n1E73sq3@'
```

where the URL format is:

```
sqs://aws_access_key_id:aws_secret_access_key@
```

Please note that you must remember to include the @ sign at the end and encode the password so it can always be parsed correctly. For example:

```python
from kombu.utils.url import quote
aws_access_key = quote("ABCDEFGHIJKLMNOPQRST")
aws_secret_key = quote("ZYXK7NiynGlTogH8Nj+P9n1E73sq3")
broker_url = "sqs://{aws_access_key}:{aws_secret_key}@".format(
    aws_access_key=aws_access_key, aws_secret_key=aws_secret_key,
)
```

The login credentials can also be set using the environment variables `AWS_ACCESS_KEY_ID` and `AWS_SECRET_ACCESS_KEY`, in that case the broker URL may only be `sqs://`. If you are using IAM roles on instances, you can set the `BROKER_URL` to: `sqs://` and kombu will attempt to retrieve access tokens from the instance metadata.

### Options

#### Region

The default region is `us-east-1` but you can select another region by configuring the `broker_transport_options` setting:

```python
broker_transport_options = {'region': 'eu-west-1'}
```

See also:

An overview of Amazon Web Services regions can be found here:

http://aws.amazon.com/about-aws/globalinfrastructure/

### Visibility Timeout

The visibility timeout defines the number of seconds to wait for the worker to acknowledge the task before the message is redelivered to another worker. Also see caveats below.
This option is set via the `broker_transport_options` setting:

```python
broker_transport_options = {'visibility_timeout': 3600} # 1 hour.
```

The default visibility timeout is 30 seconds.

**Polling Interval**

The polling interval decides the number of seconds to sleep between unsuccessful polls. This value can be either an int or a float. By default the value is *one second*: this means the worker will sleep for one second when there’s no more messages to read.

You must note that more frequent polling is also more expensive, so increasing the polling interval can save you money.

The polling interval can be set via the `broker_transport_options` setting:

```python
broker_transport_options = {'polling_interval': 0.3}
```

Very frequent polling intervals can cause *busy loops*, resulting in the worker using a lot of CPU time. If you need sub-millisecond precision you should consider using another transport, like RabbitMQ <broker-amqp>, or Redis <broker-redis>.

**Long Polling**

SQS Long Polling is enabled by default and the `WaitTimeSeconds` parameter of `ReceiveMessage` operation is set to 10 seconds.

The value of `WaitTimeSeconds` parameter can be set via the `broker_transport_options` setting:

```python
broker_transport_options = {'wait_time_seconds': 15}
```

Valid values are 0 to 20. Note that newly created queues themselves (also if created by Celery) will have the default value of 0 set for the “Receive Message Wait Time” queue property.

**Queue Prefix**

By default Celery won’t assign any prefix to the queue names, If you have other services using SQS you can configure it do so using the `broker_transport_options` setting:

```python
broker_transport_options = {'queue_name_prefix': 'celery-'}
```

**Caveats**

- If a task isn’t acknowledged within the `visibility_timeout`, the task will be redelivered to another worker and executed.
  
  This causes problems with ETA/countdown/retry tasks where the time to execute exceeds the visibility timeout; in fact if that happens it will be executed again, and again in a loop.

  So you have to increase the visibility timeout to match the time of the longest ETA you’re planning to use.
Note that Celery will redeliver messages at worker shutdown, so having a long visibility timeout will only delay the redelivery of ‘lost’ tasks in the event of a power failure or forcefully terminated workers.

Periodic tasks won’t be affected by the visibility timeout, as it is a concept separate from ETA/countdown.

The maximum visibility timeout supported by AWS as of this writing is 12 hours (43200 seconds):

```python
broker_transport_options = {'visibility_timeout': 43200}
```

- SQS doesn’t yet support worker remote control commands.
- SQS doesn’t yet support events, and so cannot be used with celery events, celerymon, or the Django Admin monitor.

Results

Multiple products in the Amazon Web Services family could be a good candidate to store or publish results with, but there’s no such result backend included at this point.

**Warning:** Don’t use the amqp result backend with SQS.

It will create one queue for every task, and the queues will not be collected. This could cost you money that would be better spent contributing an AWS result store backend back to Celery :)

Broker Overview

This is comparison table of the different transports supports, more information can be found in the documentation for each individual transport (see Broker Instructions).

<table>
<thead>
<tr>
<th>Name</th>
<th>Status</th>
<th>Monitoring</th>
<th>Remote Control</th>
</tr>
</thead>
<tbody>
<tr>
<td>RabbitMQ</td>
<td>Stable</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>Redis</td>
<td>Stable</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>Amazon SQS</td>
<td>Stable</td>
<td>No</td>
<td>No</td>
</tr>
<tr>
<td>Zookeeper</td>
<td>Experimental</td>
<td>No</td>
<td>No</td>
</tr>
</tbody>
</table>

Experimental brokers may be functional but they don’t have dedicated maintainers.

Missing monitor support means that the transport doesn’t implement events, and as such Flower, celery events, celery-mon and other event-based monitoring tools won’t work.

Remote control means the ability to inspect and manage workers at runtime using the celery inspect and celery control commands (and other tools using the remote control API).

3.2.3 First Steps with Celery

Celery is a task queue with batteries included. It’s easy to use so that you can get started without learning the full complexities of the problem it solves. It’s designed around best practices so that your product can scale and integrate with other languages, and it comes with the tools and support you need to run such a system in production.

In this tutorial you’ll learn the absolute basics of using Celery.

Learn about;
• Choosing and installing a message transport (broker).
• Installing Celery and creating your first task.
• Starting the worker and calling tasks.
• Keeping track of tasks as they transition through different states, and inspecting return values.

Celery may seem daunting at first - but don’t worry - this tutorial will get you started in no time. It’s deliberately kept simple, so as to not confuse you with advanced features. After you have finished this tutorial, it’s a good idea to browse the rest of the documentation. For example the Next Steps tutorial will showcase Celery’s capabilities.

Choosing a Broker

Celery requires a solution to send and receive messages; usually this comes in the form of a separate service called a message broker.

There are several choices available, including:

RabbitMQ

RabbitMQ is feature-complete, stable, durable and easy to install. It’s an excellent choice for a production environment. Detailed information about using RabbitMQ with Celery:

Using RabbitMQ

If you’re using Ubuntu or Debian install RabbitMQ by executing this command:

```
$ sudo apt-get install rabbitmq-server
```

Or, if you want to run it on Docker execute this:
When the command completes, the broker will already be running in the background, ready to move messages for you:

```
Starting rabbitmq-server: SUCCESS.
```

Don’t worry if you’re not running Ubuntu or Debian, you can go to this website to find similarly simple installation instructions for other platforms, including Microsoft Windows:

```
http://www.rabbitmq.com/download.html
```

### Redis

Redis is also feature-complete, but is more susceptible to data loss in the event of abrupt termination or power failures. Detailed information about using Redis:

#### Using Redis

If you want to run it on Docker execute this:

```
$ docker run -d -p 6379:6379 redis
```

### Other brokers

In addition to the above, there are other experimental transport implementations to choose from, including Amazon SQS.

See [Broker Overview](#) for a full list.

### Installing Celery

Celery is on the Python Package Index (PyPI), so it can be installed with standard Python tools like `pip` or `easy_install`:

```
$ pip install celery
```

### Application

The first thing you need is a Celery instance. We call this the *Celery application* or just `app` for short. As this instance is used as the entry-point for everything you want to do in Celery, like creating tasks and managing workers, it must be possible for other modules to import it.

In this tutorial we keep everything contained in a single module, but for larger projects you want to create a *dedicated module*.

Let’s create the file `tasks.py`:

```python
from celery import Celery

app = Celery('tasks', broker='pyamqp://guest@localhost//')

@app.task
def add(x, y):
    return x + y
```

---

**3.2. Getting Started**
The first argument to Celery is the name of the current module. This is only needed so that names can be automatically generated when the tasks are defined in the __main__ module.

The second argument is the broker keyword argument, specifying the URL of the message broker you want to use. Here using RabbitMQ (also the default option).

See Choosing a Broker above for more choices – for RabbitMQ you can use amqp://localhost, or for Redis you can use redis://localhost.

You defined a single task, called add, returning the sum of two numbers.

Running the Celery worker server

You can now run the worker by executing our program with the worker argument:

```bash
$ celery -A tasks worker --loglevel=info
```

Note: See the Troubleshooting section if the worker doesn’t start.

In production you’ll want to run the worker in the background as a daemon. To do this you need to use the tools provided by your platform, or something like supervisord (see Daemonization for more information).

For a complete listing of the command-line options available, do:

```bash
$ celery worker --help
```

There are also several other commands available, and help is also available:

```bash
$ celery help
```

Calling the task

To call our task you can use the delay() method.

This is a handy shortcut to the apply_async() method that gives greater control of the task execution (see Calling Tasks):

```python
>>> from tasks import add
>>> add.delay(4, 4)
```

The task has now been processed by the worker you started earlier. You can verify this by looking at the worker’s console output.

Calling a task returns anAsyncResult instance. This can be used to check the state of the task, wait for the task to finish, or get its return value (or if the task failed, to get the exception and traceback).

Results are not enabled by default. In order to do remote procedure calls or keep track of task results in a database, you will need to configure Celery to use a result backend. This is described in the next section.

Keeping Results

If you want to keep track of the tasks’ states, Celery needs to store or send the states somewhere. There are several built-in result backends to choose from: SQLAlchemy/Django ORM, Memcached, Redis, RPC (RabbitMQ/AMQP), and – or you can define your own.
For this example we use the `rpc` result backend, that sends states back as transient messages. The backend is specified via the `backend` argument to `Celery`, (or via the `result_backend` setting if you choose to use a configuration module):

```python
app = Celery('tasks', backend='rpc://', broker='pyamqp://')
```

Or if you want to use Redis as the result backend, but still use RabbitMQ as the message broker (a popular combination):

```python
app = Celery('tasks', backend='redis://localhost', broker='pyamqp://')
```

To read more about result backends please see `Result Backends`.

Now with the result backend configured, let’s call the task again. This time you’ll hold on to the `AsyncResult` instance returned when you call a task:

```python
>>> result = add.delay(4, 4)
```

The `ready()` method returns whether the task has finished processing or not:

```python
>>> result.ready()
False
```

You can wait for the result to complete, but this is rarely used since it turns the asynchronous call into a synchronous one:

```python
>>> result.get(timeout=1)
8
```

In case the task raised an exception, `get()` will re-raise the exception, but you can override this by specifying the `propagate` argument:

```python
>>> result.get(propagate=False)
```

If the task raised an exception, you can also gain access to the original traceback:

```python
>>> result.traceback
```

**Warning:** Backends use resources to store and transmit results. To ensure that resources are released, you must eventually call `get()` or `forget()` on EVERY `AsyncResult` instance returned after calling a task.

See `celery.result` for the complete result object reference.

### Configuration

Celery, like a consumer appliance, doesn’t need much configuration to operate. It has an input and an output. The input must be connected to a broker, and the output can be optionally connected to a result backend. However, if you look closely at the back, there’s a lid revealing loads of sliders, dials, and buttons: this is the configuration.

The default configuration should be good enough for most use cases, but there are many options that can be configured to make Celery work exactly as needed. Reading about the options available is a good idea to familiarize yourself with what can be configured. You can read about the options in the `Configuration and defaults` reference.

The configuration can be set on the app directly or by using a dedicated configuration module. As an example you can configure the default serializer used for serializing task payloads by changing the `task_serializer` setting:
app.conf.task_serializer = 'json'

If you’re configuring many settings at once you can use update:

```python
app.conf.update(
    task_serializer='json',
    accept_content=['json'], # Ignore other content
    result_serializer='json',
    timezone='Europe/Oslo',
    enable_utc=True,
)
```

For larger projects, a dedicated configuration module is recommended. Hard coding periodic task intervals and task routing options is discouraged. It is much better to keep these in a centralized location. This is especially true for libraries, as it enables users to control how their tasks behave. A centralized configuration will also allow your SysAdmin to make simple changes in the event of system trouble.

You can tell your Celery instance to use a configuration module by calling the `app.config_from_object()` method:

```python
app.config_from_object('celeryconfig')
```

This module is often called “celeryconfig”, but you can use any module name.

In the above case, a module named `celeryconfig.py` must be available to load from the current directory or on the Python path. It could look something like this:

```python
celeryconfig.py:
broker_url = 'pyamqp://'
result_backend = 'rpc://'
task_serializers = 'json'
result_serializers = 'json'
accept_content = ['json']
timezone = 'Europe/Oslo'
enable_utc = True
```

To verify that your configuration file works properly and doesn’t contain any syntax errors, you can try to import it:

```bash
$ python -m celeryconfig
```

For a complete reference of configuration options, see *Configuration and defaults*.

To demonstrate the power of configuration files, this is how you’d route a misbehaving task to a dedicated queue:

```python
celeryconfig.py:
task_routes = {
    'tasks.add': 'low-priority',
}
```

Or instead of routing it you could rate limit the task instead, so that only 10 tasks of this type can be processed in a minute (10/m):

```python
celeryconfig.py:
task_routes = {
    'tasks.add': rate_limit(10, 'minute'),
}
```
task_annotations = {
    'tasks.add': {'rate_limit': '10/m'}
}

If you’re using RabbitMQ or Redis as the broker then you can also direct the workers to set a new rate limit for the task at runtime:

```bash
$ celery -A tasks control rate_limit tasks.add 10/m
worker@example.com: OK
  new rate limit set successfully
```

See *Routing Tasks* to read more about task routing, and the `task_annotations` setting for more about annotations, or *Monitoring and Management Guide* for more about remote control commands and how to monitor what your workers are doing.

**Where to go from here**

If you want to learn more you should continue to the *Next Steps* tutorial, and after that you can read the *User Guide*.

**Troubleshooting**

There’s also a troubleshooting section in the *Frequently Asked Questions*.

**Worker doesn’t start: Permission Error**

- If you’re using Debian, Ubuntu or other Debian-based distributions:

  Debian recently renamed the `/dev/shm` special file to `/run/shm`.

  A simple workaround is to create a symbolic link:

  ```bash
  # ln -s /run/shm /dev/shm
  ```

- Others:

  If you provide any of the `--pidfile`, `--logfile` or `--statedb` arguments, then you must make sure that they point to a file or directory that’s writable and readable by the user starting the worker.

**Result backend doesn’t work or tasks are always in PENDING state**

All tasks are `PENDING` by default, so the state would’ve been better named “unknown”. Celery doesn’t update the state when a task is sent, and any task with no history is assumed to be pending (you know the task id, after all).

1) Make sure that the task doesn’t have `ignore_result` enabled.

   Enabling this option will force the worker to skip updating states.

2) Make sure the `task_ignore_result` setting isn’t enabled.

3) Make sure that you don’t have any old workers still running.

   It’s easy to start multiple workers by accident, so make sure that the previous worker is properly shut down before you start a new one.
An old worker that isn’t configured with the expected result backend may be running and is hijacking
the tasks.

The `--pidfile` argument can be set to an absolute path to make sure this doesn’t happen.

4) Make sure the client is configured with the right backend.

   If, for some reason, the client is configured to use a different backend than the worker, you won’t be
   able to receive the result. Make sure the backend is configured correctly:

   ```
   >>> result = task.delay()
   >>> print(result.backend)
   ```

### 3.2.4 Next Steps

The *First Steps with Celery* guide is intentionally minimal. In this guide I’ll demonstrate what Celery offers in more
detail, including how to add Celery support for your application and library.

This document doesn’t document all of Celery’s features and best practices, so it’s recommended that you also read
the *User Guide*

- Using Celery in your Application
- Calling Tasks
- Canvas: Designing Work-flows
- Routing
- Remote Control
- Timezone
- Optimization
- What to do now?

## Using Celery in your Application

### Our Project

Project layout:

```
proj/__init__.py
    /celery.py
    /tasks.py
```

```
proj/celery.py
```

```python
from __future__ import absolute_import, unicode_literals

from celery import Celery

app = Celery('proj',
```
In this module you created our Celery instance (sometimes referred to as the app). To use Celery within your project you simply import this instance.

- The `broker` argument specifies the URL of the broker to use.
  
  See Choosing a Broker for more information.

- The `backend` argument specifies the result backend to use,
  
  It’s used to keep track of task state and results. While results are disabled by default I use the RPC result backend here because I demonstrate how retrieving results work later, you may want to use a different backend for your application. They all have different strengths and weaknesses. If you don’t need results it’s better to disable them. Results can also be disabled for individual tasks by setting the `@task(ignore_result=True)` option.

  See Keeping Results for more information.

- The `include` argument is a list of modules to import when the worker starts. You need to add our tasks module here so that the worker is able to find our tasks.

proj/tasks.py

```python
from __future__ import absolute_import, unicode_literals

from .celery import app

@app.task
def add(x, y):
    return x + y

@app.task
def mul(x, y):
    return x * y

@app.task
def xsum(numbers):
    return sum(numbers)
```

3.2. Getting Started
Starting the worker

The **celery** program can be used to start the worker (you need to run the worker in the directory above proj):

```sh
$ celery -A proj worker -l info
```

When the worker starts you should see a banner and some messages:

```
--------------- celery
@halcyon.example.com v4.0 (latentcall)
--- ***** ----- [Configuration]
- *** --- * ---- . broker: amqp://guest@localhost:5672//
- ** ---------- . app: __main__:0x1012d8590
- ** ---------- . concurrency: 8 (processes)
- ** ---------- . events: OFF (enable -E to monitor this worker)
- ** ----------
- *** --- * ---- [Queues]
-- ******* ---- . celery: exchange:celery(direct) binding:celery
--- ***** ----- [2012-06-08 16:23:51,078: WARNING/MainProcess] celery@halcyon.example.com has started.
```

– The **broker** is the URL you specified in the broker argument in our **celery** module, you can also specify a different broker on the command-line by using the **-b** option.

– **Concurrency** is the number of prefork worker process used to process your tasks concurrently, when all of these are busy doing work new tasks will have to wait for one of the tasks to finish before it can be processed.

The default concurrency number is the number of CPU’s on that machine (including cores), you can specify a custom number using the **celery worker -c** option. There’s no recommended value, as the optimal number depends on a number of factors, but if your tasks are mostly I/O-bound then you can try to increase it, experimentation has shown that adding more than twice the number of CPU’s is rarely effective, and likely to degrade performance instead.

Including the default prefork pool, Celery also supports using Eventlet, Gevent, and running in a single thread (see **Concurrency**).

– **Events** is an option that when enabled causes Celery to send monitoring messages (events) for actions occurring in the worker. These can be used by monitor programs like **celery events**, and Flower - the real-time Celery monitor, that you can read about in the **Monitoring and Management guide**.

– **Queues** is the list of queues that the worker will consume tasks from. The worker can be told to consume from several queues at once, and this is used to route messages to specific workers as a means for Quality of Service, separation of concerns, and prioritization, all described in the **Routing Guide**.

You can get a complete list of command-line arguments by passing in the **--help** flag:

```sh
$ celery worker --help
```

These options are described in more detailed in the **Workers Guide**.

Stopping the worker

To stop the worker simply hit **Control-c**. A list of signals supported by the worker is detailed in the **Workers Guide**.

In the background

In production you’ll want to run the worker in the background, this is described in detail in the **daemonization tutorial**.
The daemonization scripts uses the **celery multi** command to start one or more workers in the background:

```
$ celery multi start w1 -A proj -l info
celery multi v4.0.0 (latentcall)
> Starting nodes...
  > w1.halcyon.local: OK
```

You can restart it too:

```
$ celery multi restart w1 -A proj -l info
celery multi v4.0.0 (latentcall)
> Stopping nodes...
  > w1.halcyon.local: TERM -> 64024
> Waiting for 1 node.....
  > w1.halcyon.local: OK
> Restarting node w1.halcyon.local: OK
celery multi v4.0.0 (latentcall)
> Stopping nodes...
  > w1.halcyon.local: TERM -> 64052
```

or stop it:

```
$ celery multi stop w1 -A proj -l info
```

The **stop** command is asynchronous so it won’t wait for the worker to shutdown. You’ll probably want to use the **stopwait** command instead, this ensures all currently executing tasks are completed before exiting:

```
$ celery multi stopwait w1 -A proj -l info
```

**Note:** **celery multi** doesn’t store information about workers so you need to use the same command-line arguments when restarting. Only the same pidfile and logfile arguments must be used when stopping.

By default it’ll create pid and log files in the current directory, to protect against multiple workers launching on top of each other you’re encouraged to put these in a dedicated directory:

```
$ mkdir -p /var/run/celery
$ mkdir -p /var/log/celery
$ celery multi start w1 -A proj -l info --pidfile=/var/run/celery/%n.pid
  --logfile=/var/log/celery/%n%I.log
```

With the multi command you can start multiple workers, and there’s a powerful command-line syntax to specify arguments for different workers too, for example:

```
$ celery multi start 10 -A proj -l info -Q:1-3 images,video -Q:4,5 data
  -Q default -L:4,5 debug
```

For more examples see the **multi** module in the API reference.

**About the --app argument**

The **--app** argument specifies the Celery app instance to use, it must be in the form of `module.path:attribute`

But it also supports a shortcut form If only a package name is specified, where it’ll try to search for the app instance, in the following order:

With **--app=proj**:

---

3.2. Getting Started 31
1) an attribute named `proj.app`, or
2) an attribute named `proj.celery`, or
3) any attribute in the module `proj` where the value is a Celery application, or

If none of these are found it’ll try a submodule named `proj.celery`:
4) an attribute named `proj.celery.app`, or
5) an attribute named `proj.celery.celery`, or
6) Any attribute in the module `proj.celery` where the value is a Celery application.

This scheme mimics the practices used in the documentation – that is, `proj:app` for a single contained module, and `proj.celery:app` for larger projects.

**Calling Tasks**

You can call a task using the `delay()` method:

```python
>>> from proj.tasks import add
>>> add.delay(2, 2)
```

This method is actually a star-argument shortcut to another method called `apply_async()`:

```python
>>> add.apply_async((2, 2))
```

The latter enables you to specify execution options like the time to run (countdown), the queue it should be sent to, and so on:

```python
>>> add.apply_async((2, 2), queue='lopri', countdown=10)
```

In the above example the task will be sent to a queue named `lopri` and the task will execute, at the earliest, 10 seconds after the message was sent.

Applying the task directly will execute the task in the current process, so that no message is sent:

```python
>>> add(2, 2)
```

These three methods - `delay()`, `apply_async()`, and applying `__call__`, represents the Celery calling API, that’s also used for signatures.

A more detailed overview of the Calling API can be found in the **Calling User Guide**.

Every task invocation will be given a unique identifier (an UUID), this is the task id.

The `delay` and `apply_async` methods return an `AsyncResult` instance, that can be used to keep track of the tasks execution state. But for this you need to enable a `result backend` so that the state can be stored somewhere.

Results are disabled by default because of the fact that there’s no result backend that suits every application, so to choose one you need to consider the drawbacks of each individual backend. For many tasks keeping the return value isn’t even very useful, so it’s a sensible default to have. Also note that result backends aren’t used for monitoring tasks and workers, for that Celery uses dedicated event messages (see **Monitoring and Management Guide**).

If you have a result backend configured you can retrieve the return value of a task:
```python
>>> res = add.delay(2, 2)
>>> res.get(timeout=1)
4
```

You can find the task’s id by looking at the `id` attribute:

```python
>>> res.id
d6b3aea2-fb9b-4ebc-8da4-848818db9114
```

You can also inspect the exception and traceback if the task raised an exception, in fact `result.get()` will propagate any errors by default:

```python
>>> res = add.delay(2)
>>> res.get(timeout=1)
```

Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
  File "/opt/devel/celery/celery/result.py", line 113, in get
      interval=interval)
  File "/opt/devel/celery/celery/backends/rpc.py", line 138, in wait_for
      raise meta['result']
TypeError: add() takes exactly 2 arguments (1 given)
```

If you don’t wish for the errors to propagate then you can disable that by passing the `propagate` argument:

```python
>>> res.get(propagate=False)
TypeError('add() takes exactly 2 arguments (1 given)',)
```

In this case it’ll return the exception instance raised instead, and so to check whether the task succeeded or failed you’ll have to use the corresponding methods on the result instance:

```python
>>> res.failed()
True
>>> res.successful()
False
```

So how does it know if the task has failed or not? It can find out by looking at the tasks `state`:

```python
>>> res.state
'FAILURE'
```

A task can only be in a single state, but it can progress through several states. The stages of a typical task can be:

```
PENDING -> STARTED -> SUCCESS
```

The started state is a special state that’s only recorded if the `task_track_started` setting is enabled, or if the @task(track_started=True) option is set for the task.

The pending state is actually not a recorded state, but rather the default state for any task id that’s unknown: this you can see from this example:

```python
>>> from proj.celery import app

>>> res = app.AsyncResult('this-id-does-not-exist')
>>> res.state
'PENDING'
```

3.2. Getting Started
If the task is retried the stages can become even more complex. To demonstrate, for a task that’s retried two times the stages would be:

PENDING -> STARTED -> RETRY -> STARTED -> RETRY -> STARTED -> SUCCESS

To read more about task states you should see the States section in the tasks user guide.

Calling tasks is described in detail in the Calling Guide.

**Canvas: Designing Work-flows**

You just learned how to call a task using the tasks delay method, and this is often all you need, but sometimes you may want to pass the signature of a task invocation to another process or as an argument to another function, for this Celery uses something called signatures.

A signature wraps the arguments and execution options of a single task invocation in such a way that it can be passed to functions or even serialized and sent across the wire.

You can create a signature for the add task using the arguments (2, 2), and a countdown of 10 seconds like this:

```python
>>> add.signature((2, 2), countdown=10)
tasks.add(2, 2)
```

There’s also a shortcut using star arguments:

```python
>>> add.s(2, 2)
tasks.add(2, 2)
```

And there’s that calling API again…

Signature instances also support the calling API, meaning they have delay and apply_async methods.

But there’s a difference in that the signature may already have an argument signature specified. The add task takes two arguments, so a signature specifying two arguments would make a complete signature:

```python
>>> s1 = add.s(2, 2)
>>> res = s1.delay()
>>> res.get()
4
```

But, you can also make incomplete signatures to create what we call partials:

```python
# incomplete partial: add(?, 2)
>>> s2 = add.s(2)
```

`s2` is now a partial signature that needs another argument to be complete, and this can be resolved when calling the signature:

```python
# resolves the partial: add(8, 2)
>>> res = s2.delay(8)
>>> res.get()
10
```

Here you added the argument 8 that was prepended to the existing argument 2 forming a complete signature of add(8, 2).
Keyword arguments can also be added later, these are then merged with any existing keyword arguments, but with new arguments taking precedence:

```
>>> s3 = add.s(2, 2, debug=True)
>>> s3.delay(debug=False)  # debug is now False.
```

As stated, signatures support the calling API: meaning that

- `sig.apply_async(args=(), kwargs={}, **options)`
  
  Calls the signature with optional partial arguments and partial keyword arguments. Also supports partial execution options.

- `sig.delay(*args, **kwargs)`
  
  Star argument version of `apply_async`. Any arguments will be prepended to the arguments in the signature, and keyword arguments is merged with any existing keys.

So this all seems very useful, but what can you actually do with these? To get to that I must introduce the canvas primitives...

**The Primitives**

- `group`
- `chain`
- `chord`
- `map`
- `starmap`
- `chunks`

These primitives are signature objects themselves, so they can be combined in any number of ways to compose complex work-flows.

**Note:** These examples retrieve results, so to try them out you need to configure a result backend. The example project above already does that (see the backend argument to `Celery`).

Let’s look at some examples:

**Groups**

A `group` calls a list of tasks in parallel, and it returns a special result instance that lets you inspect the results as a group, and retrieve the return values in order.

```
>>> from celery import group
>>> from proj.tasks import add

>>> group(add.s(i, i) for i in xrange(10)).get()
[0, 2, 4, 6, 8, 10, 12, 14, 16, 18]
```

- Partial group
Chains

Tasks can be linked together so that after one task returns the other is called:

```python
>>> from celery import chain
>>> from proj.tasks import add, mul

# (4 + 4) * 8
>>> chain(add.s(4, 4) | mul.s(8)).get()  
64
```

or a partial chain:

```python
>>> # (? + 4) * 8
>>> g = chain(add.s(4) | mul.s(8))
>>> g(4).get()  
64
```

Chains can also be written like this:

```python
>>> (add.s(4, 4) | mul.s(8)).get()  
64
```

Chords

A chord is a group with a callback:

```python
>>> from celery import chord
>>> from proj.tasks import add, xsum

>>> chord((add.s(i, i) for i in xrange(10)), xsum.s()).get()  
90
```

A group chained to another task will be automatically converted to a chord:

```python
>>> (group(add.s(i, i) for i in xrange(10)) | xsum.s()).get()  
90
```

Since these primitives are all of the signature type they can be combined almost however you want, for example:

```python
>>> upload_document.s(file) | group(apply_filter.s() for filter in filters)
```

Be sure to read more about work-flows in the *Canvas* user guide.

Routing

Celery supports all of the routing facilities provided by AMQP, but it also supports simple routing where messages are sent to named queues.

The `task_routes` setting enables you to route tasks by name and keep everything centralized in one location:
app.conf.update(
    task_routes = {
        'proj.tasks.add': {'queue': 'hipri'},
    },
)

You can also specify the queue at runtime with the queue argument to apply_async:

```python
>>> from proj.tasks import add
>>> add.apply_async((2, 2), queue='hipri')
```

You can then make a worker consume from this queue by specifying the celery worker -Q option:

```
$ celery -A proj worker -Q hipri
```

You may specify multiple queues by using a comma separated list, for example you can make the worker consume from both the default queue, and the hipri queue, where the default queue is named celery for historical reasons:

```
$ celery -A proj worker -Q hipri,celery
```

The order of the queues doesn’t matter as the worker will give equal weight to the queues.

To learn more about routing, including taking use of the full power of AMQP routing, see the Routing Guide.

**Remote Control**

If you’re using RabbitMQ (AMQP), Redis, or Qpid as the broker then you can control and inspect the worker at runtime.

For example you can see what tasks the worker is currently working on:

```
$ celery -A proj inspect active
```

This is implemented by using broadcast messaging, so all remote control commands are received by every worker in the cluster.

You can also specify one or more workers to act on the request using the --destination option. This is a comma separated list of worker host names:

```
$ celery -A proj inspect active --destination=celery@example.com
```

If a destination isn’t provided then every worker will act and reply to the request.

The celery inspect command contains commands that doesn’t change anything in the worker, it only replies information and statistics about what’s going on inside the worker. For a list of inspect commands you can execute:

```
$ celery -A proj inspect --help
```

Then there’s the celery control command, that contains commands that actually changes things in the worker at runtime:

```
$ celery -A proj control --help
```

For example you can force workers to enable event messages (used for monitoring tasks and workers):

```
$ celery -A proj control enable_events
```

When events are enabled you can then start the event dumper to see what the workers are doing:
Celery Documentation, Release 4.4.0

$ celery -A proj events --dump

or you can start the curses interface:

$ celery -A proj events

when you’re finished monitoring you can disable events again:

$ celery -A proj control disable_events

The **celery status** command also uses remote control commands and shows a list of online workers in the cluster:

$ celery -A proj status

You can read more about the **celery** command and monitoring in the *Monitoring Guide*.

**Timezone**

All times and dates, internally and in messages uses the UTC timezone.

When the worker receives a message, for example with a countdown set it converts that UTC time to local time. If you wish to use a different timezone than the system timezone then you must configure that using the `timezone` setting:

```python
app.conf.timezone = 'Europe/London'
```

**Optimization**

The default configuration isn’t optimized for throughput by default, it tries to walk the middle way between many short tasks and fewer long tasks, a compromise between throughput and fair scheduling.

If you have strict fair scheduling requirements, or want to optimize for throughput then you should read the *Optimizing Guide*.

If you’re using RabbitMQ then you can install the `librabbitmq` module: this is an AMQP client implemented in C:

$ pip install librabbitmq

**What to do now?**

Now that you have read this document you should continue to the *User Guide*.

There’s also an *API reference* if you’re so inclined.

3.3 User Guide

Release 4.4

Date Dec 16, 2019
3.3.1 Application

The Celery library must be instantiated before use, this instance is called an application (or *app* for short). The application is thread-safe so that multiple Celery applications with different configurations, components, and tasks can co-exist in the same process space.

Let’s create one now:

```python
>>> from celery import Celery
>>> app = Celery()
>>> app
<Celery __main__:0x100469fd0>
```

The last line shows the textual representation of the application: including the name of the app class (*Celery*), the name of the current main module (**main**), and the memory address of the object (0x100469fd0).

**Main Name**

Only one of these is important, and that’s the main module name. Let’s look at why that is.

When you send a task message in Celery, that message won’t contain any source code, but only the name of the task you want to execute. This works similarly to how host names work on the internet: every worker maintains a mapping of task names to their actual functions, called the *task registry*.

Whenever you define a task, that task will also be added to the local registry:

```python
>>> @app.task
def add(x, y):
    return x + y

>>> add
#@task: __main__.add>
```

and there you see that **main** again; whenever Celery isn’t able to detect what module the function belongs to, it uses the main module name to generate the beginning of the task name.

This is only a problem in a limited set of use cases:

1. If the module that the task is defined in is run as a program.
2. If the application is created in the Python shell (REPL).
For example here, where the tasks module is also used to start a worker with `app.worker_main()`:

```
from celery import Celery
app = Celery()

@app.task
def add(x, y): return x + y

if __name__ == '__main__':
    app.worker_main()
```

When this module is executed the tasks will be named starting with "__main__", but when the module is imported by another process, say to call a task, the tasks will be named starting with "tasks" (the real name of the module):

```
>>> from tasks import add
>>> add.name
'tasks.add'
```

You can specify another name for the main module:

```
>>> app = Celery('tasks')
>>> app.main
'tasks'

>>> @app.task
... def add(x, y):
...     return x + y

>>> add.name
'tasks.add'
```

See also:

- Names
- Configuration

There are several options you can set that’ll change how Celery works. These options can be set directly on the app instance, or you can use a dedicated configuration module.

The configuration is available as `app.conf`:

```
>>> app.conf.timezone
'Europe/London'
```

where you can also set configuration values directly:

```
>>> app.conf.enable_utc = True
```

or update several keys at once by using the `update` method:

```
>>> app.conf.update(
...     enable_utc=True,
...     timezone='Europe/London',
...)
```
The configuration object consists of multiple dictionaries that are consulted in order:

1. Changes made at run-time.
2. The configuration module (if any)
3. The default configuration (celery.app.defaults).

You can even add new default sources by using the `app.add_defaults()` method.

See also:
Go to the `Configuration reference` for a complete listing of all the available settings, and their default values.

### config_from_object

The `app.config_from_object()` method loads configuration from a configuration object.

This can be a configuration module, or any object with configuration attributes.

Note that any configuration that was previously set will be reset when `config_from_object()` is called. If you want to set additional configuration you should do so after.

#### Example 1: Using the name of a module

The `app.config_from_object()` method can take the fully qualified name of a Python module, or even the name of a Python attribute, for example: "celeryconfig", "myproj.config.celery", or "myproj.config: CeleryConfig".

```python
from celery import Celery
app = Celery()
app.config_from_object('celeryconfig')
```

The `celeryconfig` module may then look like this:

```python
enable_utc = True
timezone = 'Europe/London'
```

and the app will be able to use it as long as `import celeryconfig` is possible.

#### Example 2: Passing an actual module object

You can also pass an already imported module object, but this isn’t always recommended.

**Tip:** Using the name of a module is recommended as this means the module does not need to be serialized when the prefork pool is used. If you’re experiencing configuration problems or pickle errors then please try using the name of a module instead.

```python
import celeryconfig
from celery import Celery
```
Example 3: Using a configuration class/object

```python
from celery import Celery

app = Celery()

class Config:
    enable_utc = True
    timezone = 'Europe/London'

app.config_from_object(Config)
# or using the fully qualified name of the object:
# app.config_from_object('module:Config')
```

**config_from_envvar**

The `app.config_from_envvar()` takes the configuration module name from an environment variable. For example – to load configuration from a module specified in the environment variable named `CELERY_CONFIG_MODULE`:

```python
import os
from celery import Celery

#: Set default configuration module name
os.environ.setdefault('CELERY_CONFIG_MODULE', 'celeryconfig')

app = Celery()
app.config_from_envvar('CELERY_CONFIG_MODULE')
```

You can then specify the configuration module to use via the environment:

```
$ CELERY_CONFIG_MODULE="celeryconfig.prod" celery worker -l info
```

**Censored configuration**

If you ever want to print out the configuration, as debugging information or similar, you may also want to filter out sensitive information like passwords and API keys.

Celery comes with several utilities useful for presenting the configuration, one is `humanize()`:

```python
>>> app.conf.humanize(with_defaults=False, censored=True)
```

This method returns the configuration as a tabulated string. This will only contain changes to the configuration by default, but you can include the built-in default keys and values by enabling the `with_defaults` argument.

If you instead want to work with the configuration as a dictionary, you can use the `table()` method:
Please note that Celery won’t be able to remove all sensitive information, as it merely uses a regular expression to search for commonly named keys. If you add custom settings containing sensitive information you should name the keys using a name that Celery identifies as secret.

A configuration setting will be censored if the name contains any of these sub-strings:

API, TOKEN, KEY, SECRET, PASS, SIGNATURE, DATABASE

Laziness

The application instance is lazy, meaning it won’t be evaluated until it’s actually needed.

Creating a Celery instance will only do the following:

1. Create a logical clock instance, used for events.
2. Create the task registry.
3. Set itself as the current app (but not if the set_as_current argument was disabled)
4. Call the app.on_init() callback (does nothing by default).

The app.task() decorators don’t create the tasks at the point when the task is defined, instead it’ll defer the creation of the task to happen either when the task is used, or after the application has been finalized.

This example shows how the task isn’t created until you use the task, or access an attribute (in this case repr()):

```python
>>> @app.task
def add(x, y):
...    return x + y

>>> type(add)
<class 'celery.local.PromiseProxy'>

>>> add.__evaluated__()
False

>>> add   # <-- causes repr(add) to happen
<@task: __main__.add>

>>> add.__evaluated__()
True
```

Finalization of the app happens either explicitly by calling app.finalize() – or implicitly by accessing the app.tasks attribute.

Finalizing the object will:

1. Copy tasks that must be shared between apps
   Tasks are shared by default, but if the shared argument to the task decorator is disabled, then the task will be private to the app it’s bound to.
2. Evaluate all pending task decorators.
3. Make sure all tasks are bound to the current app.
   Tasks are bound to an app so that they can read default values from the configuration.
The “default app”

Celery didn’t always have applications, it used to be that there was only a module-based API, and for backwards compatibility the old API is still there until the release of Celery 5.0.

Celery always creates a special app - the “default app”, and this is used if no custom application has been instantiated.

The celery.task module is there to accommodate the old API, and shouldn’t be used if you use a custom app. You should always use the methods on the app instance, not the module based API.

For example, the old Task base class enables many compatibility features where some may be incompatible with newer features, such as task methods:

```python
from celery.task import Task  # << OLD Task base class.
from celery import Task       # << NEW base class.
```

The new base class is recommended even if you use the old module-based API.

Breaking the chain

While it’s possible to depend on the current app being set, the best practice is to always pass the app instance around to anything that needs it.

I call this the “app chain”, since it creates a chain of instances depending on the app being passed.

The following example is considered bad practice:

```python
from celery import current_app

class Scheduler(object):
    def run(self):
        app = current_app
```

Instead it should take the app as an argument:

```python
class Scheduler(object):
    def __init__(self, app):
        self.app = app
```

Internally Celery uses the `celery.app.app_or_default()` function so that everything also works in the module-based compatibility API

```python
from celery.app import app_or_default

class Scheduler(object):
    def __init__(self, app=None):
        self.app = app_or_default(app)
```

In development you can set the `CELERY_TRACE_APP` environment variable to raise an exception if the app chain breaks:

```bash
$ CELERY_TRACE_APP=1 celery worker -l info
```
Evolving the API

Celery has changed a lot from 2009 since it was initially created.

For example, in the beginning it was possible to use any callable as a task:

```python
def hello(to):
    return 'hello {0}'.format(to)

>>> from celery.execute import apply_async
>>> apply_async(hello, ('world!',))
```

You could also create a `Task` class to set certain options, or override other behavior:

```python
from celery.task import Task
from celery.registry import tasks

class Hello(Task):
    queue = 'hipri'

    def run(self, to):
        return 'hello {0}'.format(to)

tasks.register(Hello)

>>> Hello.delay('world!')
```

Later, it was decided that passing arbitrary callables was an anti-pattern, since it makes it very hard to use serializers other than pickle, and the feature was removed in 2.0, replaced by task decorators:

```python
from celery.task import task

@task(queue='hipri')
def hello(to):
    return 'hello {0}'.format(to)
```

Abstract Tasks

All tasks created using the `task()` decorator will inherit from the application’s base `Task` class.

You can specify a different base class using the `base` argument:

```python
@app.task(base=OtherTask):
def add(x, y):
    return x + y
```

To create a custom task class you should inherit from the neutral base class: `celery.Task`.

```python
from celery import Task
class DebugTask(Task):
    def __call__(self, *args, **kwargs):
        print('TASK STARTING: {0.name}{{0.request.id}}'.format(self))
        return self.run(*args, **kwargs)
```
Tip: If you override the task’s `__call__` method, then it’s very important that you also call `self.run` to execute the body of the task. Do not call `super().__call__`. The `__call__` method of the neutral base class `celery.Task` is only present for reference. For optimization, this has been unrolled into `celery.app.trace.build_tracer.trace_task` which calls `run` directly on the custom task class if no `__call__` method is defined.

The neutral base class is special because it’s not bound to any specific app yet. Once a task is bound to an app it’ll read configuration to set default values, and so on.

To realize a base class you need to create a task using the `app.task()` decorator:

```python
@app.task(base=DebugTask)
def add(x, y):
    return x + y
```

It’s even possible to change the default base class for an application by changing its `app.Task()` attribute:

```python
>>> from celery import Celery, Task
>>> app = Celery()
>>> class MyBaseTask(Task):
...    queue = 'hipri'
>>> app.Task = MyBaseTask
>>> app.Task
<unbound MyBaseTask>
>>> @app.task
... def add(x, y):
...    return x + y
>>> add
@task: __main__.add
>>> add.__class__.mro()
[<class add of <Celery __main__:0x1012b4410>>,
 <unbound MyBaseTask>,
 <unbound Task>,
 <type 'object'>]
```

### 3.3.2 Tasks

Tasks are the building blocks of Celery applications.

A task is a class that can be created out of any callable. It performs dual roles in that it defines both what happens when a task is called (sends a message), and what happens when a worker receives that message.

Every task class has a unique name, and this name is referenced in messages so the worker can find the right function to execute.

A task message is not removed from the queue until that message has been acknowledged by a worker. A worker can reserve many messages in advance and even if the worker is killed – by power failure or some other reason – the message will be redelivered to another worker.
Ideally task functions should be *idempotent*: meaning the function won’t cause unintended effects even if called multiple times with the same arguments. Since the worker cannot detect if your tasks are idempotent, the default behavior is to acknowledge the message in advance, just before it’s executed, so that a task invocation that already started is never executed again.

If your task is idempotent you can set the `acks_late` option to have the worker acknowledge the message after the task returns instead. See also the FAQ entry *Should I use retry or acks_late?*.

Note that the worker will acknowledge the message if the child process executing the task is terminated (either by the task calling `sys.exit()`, or by signal) even when `acks_late` is enabled. This behavior is by purpose as...

1. We don’t want to rerun tasks that forces the kernel to send a SIGSEGV (segmentation fault) or similar signals to the process.
2. We assume that a system administrator deliberately killing the task does not want it to automatically restart.
3. A task that allocates too much memory is in danger of triggering the kernel OOM killer, the same may happen again.
4. A task that always fails when redelivered may cause a high-frequency message loop taking down the system.

If you really want a task to be redelivered in these scenarios you should consider enabling the `task_reject_on_worker_lost` setting.

### Warning:
A task that blocks indefinitely may eventually stop the worker instance from doing any other work.

If your task does I/O then make sure you add timeouts to these operations, like adding a timeout to a web request using the `requests` library:

```python
connect_timeout, read_timeout = 5.0, 30.0
response = requests.get(URL, timeout=(connect_timeout, read_timeout))
```

*Time limits* are convenient for making sure all tasks return in a timely manner, but a time limit event will actually kill the process by force so only use them to detect cases where you haven’t used manual timeouts yet.

The default prefork pool scheduler is not friendly to long-running tasks, so if you have tasks that run for minutes/hours make sure you enable the *-Ofair* command-line argument to the `celery worker`. See *Prefork pool prefetch settings* for more information, and for the best performance route long-running and short-running tasks to dedicated workers (*Automatic routing*).

If your worker hangs then please investigate what tasks are running before submitting an issue, as most likely the hanging is caused by one or more tasks hanging on a network operation.

In this chapter you’ll learn all about defining tasks, and this is the table of contents:

- Basics
- Names
- Task Request
- Logging
- Retrying
- List of Options
- States
Basics

You can easily create a task from any callable by using the `task()` decorator:

```python
from .models import User

@app.task
def create_user(username, password):
    User.objects.create(username=username, password=password)
```

There are also many options that can be set for the task, these can be specified as arguments to the decorator:

```python
@app.task(serializer='json')
def create_user(username, password):
    User.objects.create(username=username, password=password)
```

How do I import the task decorator? And what’s “app”?

The task decorator is available on your Celery application instance, if you don’t know what this is then please read First Steps with Celery.

If you’re using Django (see First steps with Django), or you’re the author of a library then you probably want to use the `shared_task()` decorator:

```python
from celery import shared_task

@shared_task
def add(x, y):
    return x + y
```

Multiple decorators

When using multiple decorators in combination with the task decorator you must make sure that the `task` decorator is applied last (oddly, in Python this means it must be first in the list):

```python
@app.task
@decorator2
@decorator1
def add(x, y):
    return x + y
```
Bound tasks

A task being bound means the first argument to the task will always be the task instance (self), just like Python bound methods:

```python
logger = get_task_logger(__name__)
@task(bind=True)
def add(self, x, y):
    logger.info(self.request.id)
```

Bound tasks are needed for retries (using `app.Task.retry()`), for accessing information about the current task request, and for any additional functionality you add to custom task base classes.

Task inheritance

The `base` argument to the task decorator specifies the base class of the task:

```python
import celery
class MyTask(celery.Task):
    def on_failure(self, exc, task_id, args, kwargs, einfo):
        print(('{} failed: {}').format(task_id, exc))
@task(base=MyTask)
def add(x, y):
    raise KeyError()
```

Names

Every task must have a unique name.

If no explicit name is provided the task decorator will generate one for you, and this name will be based on 1) the module the task is defined in, and 2) the name of the task function.

Example setting explicit name:

```python
>>> @app.task(name='sum-of-two-numbers')
>>> def add(x, y):
...     return x + y

>>> add.name
'sum-of-two-numbers'
```

A best practice is to use the module name as a name-space, this way names won’t collide if there’s already a task with that name defined in another module.

```python
>>> @app.task(name='tasks.add')
>>> def add(x, y):
...     return x + y
```

You can tell the name of the task by investigating its `.name` attribute:
The name we specified here (tasks.add) is exactly the name that would’ve been automatically generated for us if the task was defined in a module named tasks.py:

tasks.py:

```python
@app.task
def add(x, y):
    return x + y
```

>>> from tasks import add
>>> add.name
'tasks.add'

## Automatic naming and relative imports

### Absolute Imports

The best practice for developers targeting Python 2 is to add the following to the top of every module:

```python
from __future__ import absolute_import
```

This will force you to always use absolute imports so you will never have any problems with tasks using relative names.

Absolute imports are the default in Python 3 so you don’t need this if you target that version.

Relative imports and automatic name generation don’t go well together, so if you’re using relative imports you should set the name explicitly.

For example if the client imports the module "myapp.tasks" as ".tasks", and the worker imports the module as "myapp.tasks", the generated names won’t match and an `NotRegistered` error will be raised by the worker.

This is also the case when using Django and using `project.myapp`-style naming in `INSTALLED_APPS`:

```python
INSTALLED_APPS = ['project.myapp']
```

If you install the app under the name `project.myapp` then the tasks module will be imported as `project.myapp.tasks`, so you must make sure you always import the tasks using the same name:

```python
>>> from project.myapp.tasks import mytask  # << GOOD
>>> from myapp.tasks import mytask         # << BAD!!!
```

The second example will cause the task to be named differently since the worker and the client imports the modules under different names:

```python
>>> from project.myapp.tasks import mytask
>>> mytask.name
'project.myapp.tasks.mytask'
>>> from myapp.tasks import mytask
```

(continues on next page)
>>> mytask.name
'myapp.tasks.mytask'

For this reason you must be consistent in how you import modules, and that is also a Python best practice.

Similarly, you shouldn’t use old-style relative imports:

```python
from module import foo  # BAD!
from proj.module import foo  # GOOD!
```

New-style relative imports are fine and can be used:

```python
from .module import foo  # GOOD!
```

If you want to use Celery with a project already using these patterns extensively and you don’t have the time to refactor
the existing code then you can consider specifying the names explicitly instead of relying on the automatic naming:

```python
@task(name='proj.tasks.add')
def add(x, y):
    return x + y
```

### Changing the automatic naming behavior

New in version 4.0.

There are some cases when the default automatic naming isn’t suitable. Consider having many tasks within many
different modules:

```
project/
    /__init__.py
    /celery.py
/moduleA/
    /__init__.py
    /tasks.py
/moduleB/
    /__init__.py
    /tasks.py
```

Using the default automatic naming, each task will have a generated name like `moduleA.tasks.taskA`, `moduleA.tasks.taskB`, `moduleB.tasks.test`, and so on. You may want to get rid of having tasks in all task names. As pointed above, you can explicitly give names for all tasks, or you can change the automatic naming behavior by overriding `app.gen_task_name()`. Continuing with the example, `celery.py` may contain:

```python
from celery import Celery

class MyCelery(Celery):

    def gen_task_name(self, name, module):
        if module.endswith('.tasks'):
            module = module[:-6]
        return super(MyCelery, self).gen_task_name(name, module)

app = MyCelery('main')
So each task will have a name like `moduleA.taskA`, `moduleA.taskB` and `moduleB.test`.

**Warning:** Make sure that your `app.gen_task_name()` is a pure function: meaning that for the same input it must always return the same output.

---

**Task Request**

`app.Task.request` contains information and state related to the currently executing task.

The request defines the following attributes:

- **id** The unique id of the executing task.
- **group** The unique id of the task’s `group`, if this task is a member.
- **chord** The unique id of the chord this task belongs to (if the task is part of the header).
- **correlation_id** Custom ID used for things like de-duplication.
- **args** Positional arguments.
- **kwargs** Keyword arguments.
- **origin** Name of host that sent this task.
- **retries** How many times the current task has been retried. An integer starting at 0.
- **is_eager** Set to `True` if the task is executed locally in the client, not by a worker.
- **eta** The original ETA of the task (if any). This is in UTC time (depending on the `enable_utc` setting).
- **expires** The original expiry time of the task (if any). This is in UTC time (depending on the `enable_utc` setting).
- **hostname** Node name of the worker instance executing the task.
- **delivery_info** Additional message delivery information. This is a mapping containing the exchange and routing key used to deliver this task. Used by for example `app.Task.retry()` to resend the task to the same destination queue. Availability of keys in this dict depends on the message broker used.
- **reply-to** Name of queue to send replies back to (used with RPC result backend for example).
- **called_directly** This flag is set to true if the task wasn’t executed by the worker.
- **timelimit** A tuple of the current `(soft, hard)` time limits active for this task (if any).
- **callbacks** A list of signatures to be called if this task returns successfully.
- **errback** A list of signatures to be called if this task fails.
- **utc** Set to true the caller has UTC enabled (`enable_utc`).

New in version 3.1.

- **headers** Mapping of message headers sent with this task message (may be `None`).
- **reply_to** Where to send reply to (queue name).
- **correlation_id** Usually the same as the task id, often used in amqp to keep track of what a reply is for.

New in version 4.0.

- **root_id** The unique id of the first task in the workflow this task is part of (if any).
- **parent_id** The unique id of the task that called this task (if any).
chain  Reversed list of tasks that form a chain (if any). The last item in this list will be the next task to succeed the current task. If using version one of the task protocol the chain tasks will be in request.callbacks instead.

Example

An example task accessing information in the context is:

```python
@app.task(bind=True)
def dump_context(self, x, y):
    print('Executing task id {0.id}, args: {0.args!r} kwargs: {0.kwargs!r}'.format(self.request))
```

The bind argument means that the function will be a “bound method” so that you can access attributes and methods on the task type instance.

Logging

The worker will automatically set up logging for you, or you can configure logging manually.

A special logger is available named “celery.task”, you can inherit from this logger to automatically get the task name and unique id as part of the logs.

The best practice is to create a common logger for all of your tasks at the top of your module:

```python
from celery.utils.log import get_task_logger
logger = get_task_logger(__name__)

@app.task
def add(x, y):
    logger.info('Adding {0} + {1}'.format(x, y))
    return x + y
```

Celery uses the standard Python logger library, and the documentation can be found here.

You can also use print(), as anything written to standard out/-err will be redirected to the logging system (you can disable this, see worker_redirect_stdouts).

Note:  The worker won’t update the redirection if you create a logger instance somewhere in your task or task module.

If you want to redirect sys.stdout and sys.stderr to a custom logger you have to enable this manually, for example:

```python
import sys
logger = get_task_logger(__name__)

@app.task(bind=True)
def add(self, x, y):
    old_outs = sys.stdout, sys.stderr
    rlevel = self.app.conf.worker_redirect_stdouts_level
    try:
        self.app.log.redirect_stdouts_to_logger(logger, rlevel)
        print('Adding {0} + {1}'.format(x, y))
    finally:
        sys.stdout, sys.stderr = old_outs
```

(continues on next page)
```
return x + y
finally:
    sys.stdout, sys.stderr = old_outs
```

**Note:** If a specific Celery logger you need is not emitting logs, you should check that the logger is propagating properly. In this example “celery.app.trace” is enabled so that “succeeded in” logs are emitted:

```python
import celery
import logging

@celery.signals.after_setup_logger.connect
def on_after_setup_logger(**kwargs):
    logger = logging.getLogger('celery')
    logger.propagate = True
    logger = logging.getLogger('celery.app.trace')
    logger.propagate = True
```

**Note:** If you want to completely disable Celery logging configuration, use the `setup_logging` signal:

```python
import celery

@celery.signals.setup_logging.connect
def on_setup_logging(**kwargs):
    pass
```

### Argument checking

**New in version 4.0.**

Celery will verify the arguments passed when you call the task, just like Python does when calling a normal function:

```python
>>> @app.task
... def add(x, y):
...     return x + y

# Calling the task with two arguments works:
>>> add.delay(8, 8)
<AsyncResult: f59d71ca-1549-43e0-be41-4e8821a83c0c>

# Calling the task with only one argument fails:
>>> add.delay(8)
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
  File "celery/app/task.py", line 376, in delay
    return self.apply_async(args, kwargs)
  File "celery/app/task.py", line 485, in apply_async
    check_arguments(**(args or {}), **(kwargs or {}))
TypeError: add() takes exactly 2 arguments (1 given)
```

You can disable the argument checking for any task by setting its `typing` attribute to `False`:

3.3. User Guide 55
>>> @app.task(typing=False)
... def add(x, y):
...     return x + y

# Works locally, but the worker receiving the task will raise an error.
>>> add.delay(8)
<AsyncResult: f59d71ca-1549-43e0-be41-4e8821a83c0c>

### Hiding sensitive information in arguments

New in version 4.0.

When using `task_protocol` 2 or higher (default since 4.0), you can override how positional arguments and keyword arguments are represented in logs and monitoring events using the `argsrepr` and `kwargsrepr` calling arguments:

```python
>>> add.apply_async((2, 3), argsrepr='(<secret-x>, <secret-y>)')

>>> charge.s(account, card='1234 5678 1234 5678').set(... kwargsrepr=repr({'card': '**** **** **** 5678'}))
```  

**Warning:** Sensitive information will still be accessible to anyone able to read your task message from the broker, or otherwise able intercept it.

For this reason you should probably encrypt your message if it contains sensitive information, or in this example with a credit card number the actual number could be stored encrypted in a secure store that you retrieve and decrypt in the task itself.

### Retrying

`app.Task.retry()` can be used to re-execute the task, for example in the event of recoverable errors.

When you call `retry` it’ll send a new message, using the same task-id, and it’ll take care to make sure the message is delivered to the same queue as the originating task.

When a task is retried this is also recorded as a task state, so that you can track the progress of the task using the result instance (see `States`).

Here’s an example using `retry`:

```python
@app.task(bind=True)
def send_twitter_status(self, oauth, tweet):
    try:
        twitter = Twitter(oauth)
twitter.update_status(tweet)
    except (Twitter.FailWhaleError, Twitter.LoginError) as exc:
        raise self.retry(exc=exc)
```  

**Note:** The `app.Task.retry()` call will raise an exception so any code after the retry won’t be reached. This is the `Retry` exception, it isn’t handled as an error but rather as a semi-predicate to signify to the worker that the task is to be retried, so that it can store the correct state when a result backend is enabled.
This is normal operation and always happens unless the `throw` argument to `retry` is set to `False`.

The bind argument to the task decorator will give access to `self` (the task type instance).

The `exc` argument is used to pass exception information that’s used in logs, and when storing task results. Both the exception and the traceback will be available in the task state (if a result backend is enabled).

If the task has a `max_retries` value the current exception will be re-raised if the max number of retries has been exceeded, but this won’t happen if:

- An `exc` argument wasn’t given.
  
  In this case the `MaxRetriesExceededError` exception will be raised.

- There’s no current exception
  
  If there’s no original exception to re-raise the `exc` argument will be used instead, so:

  ```python
  self.retry(exc=Twitter.LoginError())
  ```

  will raise the `exc` argument given.

### Using a custom retry delay

When a task is to be retried, it can wait for a given amount of time before doing so, and the default delay is defined by the `default_retry_delay` attribute. By default this is set to 3 minutes. Note that the unit for setting the delay is in seconds (int or float).

You can also provide the `countdown` argument to `retry()` to override this default.

```python
@task(bind=True, default_retry_delay=30 * 60)  # retry in 30 minutes.
def add(self, x, y):
    try:
        something_raising()
    except Exception as exc:
        # overrides the default delay to retry after 1 minute
        raise self.retry(exc=exc, countdown=60)
```

### Automatic retry for known exceptions

New in version 4.0.

Sometimes you just want to retry a task whenever a particular exception is raised.

Fortunately, you can tell Celery to automatically retry a task using `autoretry_for` argument in the `task()` decorator:

```python
from twitter.exceptions import FailWhaleError

@task(autoretry_for=(FailWhaleError,))
def refresh_timeline(user):
    return twitter.refresh_timeline(user)
```

If you want to specify custom arguments for an internal `retry()` call, pass `retry_kwargs` argument to `task()` decorator:
Celery Documentation, Release 4.4.0

```python
@app.task(autoretry_for=(FailWhaleError,),
          retry_kwargs=({'max_retries': 5}))
def refresh_timeline(user):
    return twitter.refresh_timeline(user)
```

This is provided as an alternative to manually handling the exceptions, and the example above will do the same as wrapping the task body in a `try...except` statement:

```python
@app.task
def refresh_timeline(user):
    try:
        twitter.refresh_timeline(user)
    except FailWhaleError as exc:
        raise div.retry(exc=exc, max_retries=5)
```

If you want to automatically retry on any error, simply use:

```python
@app.task(autoretry_for=(Exception,))
def x():
    ...
```

New in version 4.2.

If your tasks depend on another service, like making a request to an API, then it’s a good idea to use exponential backoff to avoid overwhelming the service with your requests. Fortunately, Celery’s automatic retry support makes it easy. Just specify the `retry_backoff` argument, like this:

```python
from requests.exceptions import RequestException

@app.task(autoretry_for=(RequestException,), retry_backoff=True)
def x():
    ...
```

By default, this exponential backoff will also introduce random jitter to avoid having all the tasks run at the same moment. It will also cap the maximum backoff delay to 10 minutes. All these settings can be customized via options documented below.

Task. `autoretry_for`
A list/tuple of exception classes. If any of these exceptions are raised during the execution of the task, the task will automatically be retried. By default, no exceptions will be autoretried.

Task. `retry_kwargs`
A dictionary. Use this to customize how autoretries are executed. Note that if you use the exponential backoff options below, the `countdown` task option will be determined by Celery’s autoretry system, and any `countdown` included in this dictionary will be ignored.

Task. `retry_backoff`
A boolean, or a number. If this option is set to `True`, autoretries will be delayed following the rules of exponential backoff. The first retry will have a delay of 1 second, the second retry will have a delay of 2 seconds, the third will delay 4 seconds, the fourth will delay 8 seconds, and so on. (However, this delay value is modified by `retry_jitter`, if it is enabled.) If this option is set to a number, it is used as a delay factor. For example, if this option is set to 3, the first retry will delay 3 seconds, the second will delay 6 seconds, the third will delay 12 seconds, the fourth will delay 24 seconds, and so on. By default, this option is set to `False`, and autoretries will not be delayed.

Task. `retry_backoff_max`
A number. If `retry_backoff` is enabled, this option will set a maximum delay in seconds between task autoretries. By default, this option is set to `600`, which is 10 minutes.
Task\texttt{.retry\_jitter}

A boolean. \texttt{Jitter} is used to introduce randomness into exponential backoff delays, to prevent all tasks in the queue from being executed simultaneously. If this option is set to \texttt{True}, the delay value calculated by \texttt{retry\_backoff} is treated as a maximum, and the actual delay value will be a random number between zero and that maximum. By default, this option is set to \texttt{True}.

**List of Options**

The task decorator can take a number of options that change the way the task behaves, for example you can set the rate limit for a task using the \texttt{rate\_limit} option.

Any keyword argument passed to the task decorator will actually be set as an attribute of the resulting task class, and this is a list of the built-in attributes.

**General**

**Task\texttt{.name}**

The name the task is registered as.

You can set this name manually, or a name will be automatically generated using the module and class name.

See also \texttt{Names}.

**Task\texttt{.request}**

If the task is being executed this will contain information about the current request. Thread local storage is used.

See \texttt{Task Request}.

**Task\texttt{.max\_retries}**

Only applies if the task calls \texttt{self.retry} or if the task is decorated with the \texttt{autoretry\_for} argument.

The maximum number of attempted retries before giving up. If the number of retries exceeds this value a \texttt{MaxRetriesExceededError} exception will be raised.

\begin{quote}
\textbf{Note:} You have to call \texttt{retry()} manually, as it won’t automatically retry on exception.
\end{quote}

The default is 3. A value of \texttt{None} will disable the retry limit and the task will retry forever until it succeeds.

**Task\texttt{.throws}**

Optional tuple of expected error classes that shouldn’t be regarded as an actual error.

Errors in this list will be reported as a failure to the result backend, but the worker won’t log the event as an error, and no traceback will be included.

Example:

\begin{verbatim}
@task(throws=(KeyError, HttpNotFound)):
def get_foo():
    something()
\end{verbatim}

Error types:

- Expected errors (in Task.throws)
  Logged with severity INFO, traceback excluded.

- Unexpected errors
  Logged with severity ERROR, with traceback included.
Task `default_retry_delay`  
Default time in seconds before a retry of the task should be executed. Can be either `int` or `float`. Default is a three minute delay.

Task `rate_limit`  
Set the rate limit for this task type (limits the number of tasks that can be run in a given time frame). Tasks will still complete when a rate limit is in effect, but it may take some time before it’s allowed to start.

If this is `None` no rate limit is in effect. If it is an integer or float, it is interpreted as “tasks per second”.

The rate limits can be specified in seconds, minutes or hours by appending “/s”, “/m” or “/h” to the value. Tasks will be evenly distributed over the specified time frame.

Example: “100/m” (hundred tasks a minute). This will enforce a minimum delay of 600ms between starting two tasks on the same worker instance.

Default is the `task_default_rate_limit` setting: if not specified means rate limiting for tasks is disabled by default.

Note that this is a per worker instance rate limit, and not a global rate limit. To enforce a global rate limit (e.g., for an API with a maximum number of requests per second), you must restrict to a given queue.

Task `time_limit`  
The hard time limit, in seconds, for this task. When not set the workers default is used.

Task `soft_time_limit`  
The soft time limit for this task. When not set the workers default is used.

Task `ignore_result`  
Don’t store task state. Note that this means you can’t use `AsyncResult` to check if the task is ready, or get its return value.

Task `store_errors_even_if_ignored`  
If `True`, errors will be stored even if the task is configured to ignore results.

Task `serializer`  
A string identifying the default serialization method to use. Defaults to the `task_serializer` setting. Can be `pickle`, `json`, `yaml`, or any custom serialization methods that have been registered with `kombu.serialization.registry`.

Please see `Serializers` for more information.

Task `compression`  
A string identifying the default compression scheme to use.

Defaults to the `task_compression` setting. Can be `gzip`, or `bzip2`, or any custom compression schemes that have been registered with the `kombu.compression.registry`.

Please see `Compression` for more information.

Task `backend`  
The result store backend to use for this task. An instance of one of the backend classes in `celery.backends`. Defaults to `app.backend`, defined by the `result_backend` setting.

Task `acks_late`  
If set to `True` messages for this task will be acknowledged after the task has been executed, not just before (the default behavior).

Note: This means the task may be executed multiple times should the worker crash in the middle of execution. Make sure your tasks are idempotent.

The global default can be overridden by the `task_acks_late` setting.
**Task**. **track_started**

If `True` the task will report its status as “started” when the task is executed by a worker. The default value is `False` as the normal behavior is to not report that level of granularity. Tasks are either pending, finished, or waiting to be retried. Having a “started” status can be useful for when there are long running tasks and there’s a need to report what task is currently running.

The host name and process id of the worker executing the task will be available in the state meta-data (e.g., `result.info['pid']`) The global default can be overridden by the `task_track_started` setting.

See also:

The API reference for `Task`.

**States**

Celery can keep track of the tasks current state. The state also contains the result of a successful task, or the exception and traceback information of a failed task.

There are several result backends to choose from, and they all have different strengths and weaknesses (see Result Backends).

During its lifetime a task will transition through several possible states, and each state may have arbitrary meta-data attached to it. When a task moves into a new state the previous state is forgotten about, but some transitions can be deduced, (e.g., a task now in the `FAILED` state, is implied to have been in the `STARTED` state at some point).

There are also sets of states, like the set of `FAILURE_STATES`, and the set of `READY_STATES`. The client uses the membership of these sets to decide whether the exception should be re-raised (`PROPAGATE_STATES`), or whether the state can be cached (it can if the task is ready).

You can also define **Custom states**.

**Result Backends**

If you want to keep track of tasks or need the return values, then Celery must store or send the states somewhere so that they can be retrieved later. There are several built-in result backends to choose from: SQLAlchemy/Django ORM, Memcached, RabbitMQ/QPid (`rpc`), and Redis – or you can define your own.

No backend works well for every use case. You should read about the strengths and weaknesses of each backend, and choose the most appropriate for your needs.

**Warning:** Backends use resources to store and transmit results. To ensure that resources are released, you must eventually call `get()` or `forget()` on EVERY `AsyncResult` instance returned after calling a task.

See also:

*Task result backend settings*

**RPC Result Backend (RabbitMQ/QPid)**

The RPC result backend (`rpc://`) is special as it doesn’t actually store the states, but rather sends them as messages. This is an important difference as it means that a result can only be retrieved once, and only by the client that initiated the task. Two different processes can’t wait for the same result.
Even with that limitation, it is an excellent choice if you need to receive state changes in real-time. Using messaging means the client doesn’t have to poll for new states.

The messages are transient (non-persistent) by default, so the results will disappear if the broker restarts. You can configure the result backend to send persistent messages using the `result_persistent` setting.

**Database Result Backend**

Keeping state in the database can be convenient for many, especially for web applications with a database already in place, but it also comes with limitations.

- Polling the database for new states is expensive, and so you should increase the polling intervals of operations, such as `result.get()`.
- Some databases use a default transaction isolation level that isn’t suitable for polling tables for changes.
  
  In MySQL the default transaction isolation level is `REPEATABLE-READ`: meaning the transaction won’t see changes made by other transactions until the current transaction is committed.
  
  Changing that to the `READ-COMMITTED` isolation level is recommended.

**Built-in States**

**PENDING**

Task is waiting for execution or unknown. Any task id that’s not known is implied to be in the pending state.

**STARTED**

Task has been started. Not reported by default, to enable please see `app.Task.track_started`.

- **meta-data** `pid` and `hostname` of the worker process executing the task.

**SUCCESS**

Task has been successfully executed.

- **meta-data** `result` contains the return value of the task.
- **propagates** Yes
- **ready** Yes

**FAILURE**

Task execution resulted in failure.

- **meta-data** `result` contains the exception occurred, and `traceback` contains the backtrace of the stack at the point when the exception was raised.
- **propagates** Yes
RETRY

Task is being retried.

- **meta-data**: result contains the exception that caused the retry, and traceback contains the backtrace of the stack at the point when the exceptions was raised.
- **propagates**: No

REMOVED

Task has been revoked.

- **propagates**: Yes

Custom states

You can easily define your own states, all you need is a unique name. The name of the state is usually an uppercase string. As an example you could have a look at the abortable tasks which defines a custom ABORTED state.

Use `update_state()` to update a task’s state:

```python
@app.task(bind=True)
def upload_files(self, filenames):
    for i, file in enumerate(filenames):
        if not self.request.called_directly:
            self.update_state(state='PROGRESS',
                              meta={'current': i, 'total': len(filenames)})
```

Here I created the state “PROGRESS“, telling any application aware of this state that the task is currently in progress, and also where it is in the process by having current and total counts as part of the state meta-data. This can then be used to create progress bars for example.

Creating pickleable exceptions

A rarely known Python fact is that exceptions must conform to some simple rules to support being serialized by the pickle module.

Tasks that raise exceptions that aren’t pickleable won’t work properly when Pickle is used as the serializer.

To make sure that your exceptions are pickleable the exception MUST provide the original arguments it was instantiated with in its .args attribute. The simplest way to ensure this is to have the exception call `Exception.__init__`.

Let’s look at some examples that work, and one that doesn’t:

```python
# OK:
class HttpError(Exception):
    pass

# BAD:
class HttpError(Exception):
    def __init__(self, status_code):
        self.status_code = status_code
```

(continues on next page)
# OK:

class HttpError(Exception):
    
    def __init__(self, status_code):
        self.status_code = status_code
        Exception.__init__(self, status_code)  # <-- REQUIRED

So the rule is: For any exception that supports custom arguments *args, `Exception.__init__(self, *args)` must be used.

There’s no special support for keyword arguments, so if you want to preserve keyword arguments when the exception is unpickled you have to pass them as regular args:

class HttpError(Exception):
    
    def __init__(self, status_code, headers=None, body=None):
        self.status_code = status_code
        self.headers = headers
        self.body = body
        super(HttpError, self).__init__(status_code, headers, body)

Semipredicates

The worker wraps the task in a tracing function that records the final state of the task. There are a number of exceptions that can be used to signal this function to change how it treats the return of the task.

**Ignore**

The task may raise `Ignore` to force the worker to ignore the task. This means that no state will be recorded for the task, but the message is still acknowledged (removed from queue).

This can be used if you want to implement custom revoke-like functionality, or manually store the result of a task.

Example keeping revoked tasks in a Redis set:

```python
from celery.exceptions import Ignore

@app.task(bind=True)
def some_task(self):
    if redis.ismember('tasks.revoked', self.request.id):
        raise Ignore()
```

Example that stores results manually:

```python
from celery import states
from celery.exceptions import Ignore

@app.task(bind=True)
def get_tweets(self, user):
    timeline = twitter.get_timeline(user)
    if not self.request.called_directly:
        self.update_state(state=states.SUCCESS, meta=timeline)
        raise Ignore()
```
Reject

The task may raise `Reject` to reject the task message using AMQPs `basic_reject` method. This won’t have any effect unless `Task.acks_late` is enabled.

Rejecting a message has the same effect as acking it, but some brokers may implement additional functionality that can be used. For example RabbitMQ supports the concept of Dead Letter Exchanges where a queue can be configured to use a dead letter exchange that rejected messages are redelivered to.

Reject can also be used to re-queue messages, but please be very careful when using this as it can easily result in an infinite message loop.

Example using reject when a task causes an out of memory condition:

```python
import errno
from celery.exceptions import Reject

@app.task(bind=True, acks_late=True)
def render_scene(self, path):
    file = get_file(path)
    try:
        renderer.render_scene(file)
        # if the file is too big to fit in memory
        # we reject it so that it's redelivered to the dead letter exchange
        # and we can manually inspect the situation.
        except MemoryError as exc:
            raise Reject(exc, requeue=False)
        except OSError as exc:
            if exc.errno == errno.ENOMEM:
                raise Reject(exc, requeue=False)
        # For any other error we retry after 10 seconds.
        except Exception as exc:
            raise self.retry(exc, countdown=10)

Example re-queuing the message:

```python
from celery.exceptions import Reject

@app.task(bind=True, acks_late=True)
def requeues(self):
    if not self.request.delivery_info['redelivered']:
        raise Reject('no reason', requeue=True)
    print('received two times')
```

Consult your broker documentation for more details about the `basic_reject` method.

Retry

The `Retry` exception is raised by the `Task.retry` method to tell the worker that the task is being retried.

Custom task classes

All tasks inherit from the `app.Task` class. The `run()` method becomes the task body.

As an example, the following code,
```python
@app.task
def add(x, y):
    return x + y
```

will do roughly this behind the scenes:

```python
class _AddTask(app.Task):
    def run(self, x, y):
        return x + y
add = app.tasks[_AddTask.name]
```

### Instantiation

A task is **not** instantiated for every request, but is registered in the task registry as a global instance.

This means that the `__init__` constructor will only be called once per process, and that the task class is semantically closer to an Actor.

If you have a task,

```python
from celery import Task
class NaiveAuthenticateServer(Task):
    def __init__(self):
        self.users = {'george': 'password'}
    def run(self, username, password):
        try:
            return self.users[username] == password
        except KeyError:
            return False
```

And you route every request to the same process, then it will keep state between requests.

This can also be useful to cache resources, for example, a base Task class that caches a database connection:

```python
from celery import Task
class DatabaseTask(Task):
    _db = None

    @property
def db(self):
        if self._db is None:
            self._db = Database.connect()
        return self._db
```

### Per task usage

The above can be added to each task like this:
@app.task(base=DatabaseTask)
def process_rows():
    for row in process_rows.db.table.all():
        process_row(row)

The `db` attribute of the `process_rows` task will then always stay the same in each process.

**App-wide usage**

You can also use your custom class in your whole Celery app by passing it as the `task_cls` argument when instantiating the app. This argument should be either a string giving the python path to your Task class or the class itself:

```python
from celery import Celery

app = Celery('tasks', task_cls='your.module.path:DatabaseTask')
```

This will make all your tasks declared using the decorator syntax within your app to use your `DatabaseTask` class and will all have a `db` attribute.

The default value is the class provided by Celery: `celery.app.task:Task`.

**Handlers**

**after_return** *(self, status, retval, task_id, args, kwargs, einfo)*

Handler called after the task returns.

**Parameters**

- `status` – Current task state.
- `retval` – Task return value/exception.
- `task_id` – Unique id of the task.
- `args` – Original arguments for the task that returned.
- `kwargs` – Original keyword arguments for the task that returned.

**Keyword Arguments**

- `einfo` – `ExceptionInfo` instance, containing the traceback (if any).

The return value of this handler is ignored.

**on_failure** *(self, exc, task_id, args, kwargs, einfo)*

This is run by the worker when the task fails.

**Parameters**

- `exc` – The exception raised by the task.
- `task_id` – Unique id of the failed task.
- `args` – Original arguments for the task that failed.
- `kwargs` – Original keyword arguments for the task that failed.

**Keyword Arguments**

- `einfo` – `ExceptionInfo` instance, containing the traceback.

The return value of this handler is ignored.
on_retry (self, exc, task_id, args, kwargs, einfo)
This is run by the worker when the task is to be retried.

Parameters

- exc – The exception sent to retry().
- task_id – Unique id of the retried task.
- args – Original arguments for the retried task.
- kwargs – Original keyword arguments for the retried task.

Keyword Arguments einfo – ExceptionInfo instance, containing the traceback.

The return value of this handler is ignored.

on_success (self, retval, task_id, args, kwargs)
Run by the worker if the task executes successfully.

Parameters

- retval – The return value of the task.
- task_id – Unique id of the executed task.
- args – Original arguments for the executed task.
- kwargs – Original keyword arguments for the executed task.

The return value of this handler is ignored.

Requests and custom requests

Upon receiving a message to run a task, the worker creates a request to represent such demand.

Custom task classes may override which request class to use by changing the attribute celery.app.task.Task. Request. You may either assign the custom request class itself, or its fully qualified name.

The request has several responsibilities. Custom request classes should cover them all – they are responsible to actually run and trace the task. We strongly recommend to inherit from celery.worker.request.Request.

When using the pre-forking worker, the methods on_timeout() and on_failure() are executed in the main worker process. An application may leverage such facility to detect failures which are not detected using celery.app.task.Task.on_failure().

As an example, the following custom request detects and logs hard time limits, and other failures.

```python
import logging
from celery.worker.request import Request

logger = logging.getLogger('my.package')

class MyRequest(Request):
    'A minimal custom request to log failures and hard time limits.'

    def on_timeout(self, soft, timeout):
        super(MyRequest, self).on_timeout(soft, timeout)
        if not soft:
            logger.warning(
                'A hard timeout was enforced for task %s',
                self.task.name
            )
```

(continues on next page)
def on_failure(self, exc_info, send_failed_event=True, return_ok=False):
    super(Request, self).on_failure(
        exc_info,
        send_failed_event=send_failed_event,
        return_ok=return_ok
    )
    logger.warning('Failure detected for task %s',
        self.task.name
    )

class MyTask(Task):
    Request = MyRequest  # you can use a FQN 'my.package:MyRequest'

@app.task(base=MyTask)
def some_longrunning_task():
    # use your imagination

How it works

Here come the technical details. This part isn’t something you need to know, but you may be interested.

All defined tasks are listed in a registry. The registry contains a list of task names and their task classes. You can investigate this registry yourself:

```python
>>> from proj.celery import app
>>> app.tasks
{'celery.chord_unlock':
    <@task: celery.chord_unlock>,
'celery.backend_cleanup':
    <@task: celery.backend_cleanup>,
'celery.chord':
    <@task: celery.chord>}
```

This is the list of tasks built into Celery. Note that tasks will only be registered when the module they’re defined in is imported.

The default loader imports any modules listed in the imports setting.

The app.task() decorator is responsible for registering your task in the applications task registry.

When tasks are sent, no actual function code is sent with it, just the name of the task to execute. When the worker then receives the message it can look up the name in its task registry to find the execution code.

This means that your workers should always be updated with the same software as the client. This is a drawback, but the alternative is a technical challenge that’s yet to be solved.

Tips and Best Practices

Ignore results you don’t want

If you don’t care about the results of a task, be sure to set the ignore_result option, as storing results wastes time and resources.
@app.task(ignore_result=True)
def mytask():
    something()

Results can even be disabled globally using the `task_ignore_result` setting.

Results can be enabled/disabled on a per-execution basis, by passing the `ignore_result` boolean parameter, when calling `apply_async` or `delay`.

@app.task
def mytask(x, y):
    return x + y

# No result will be stored
result = mytask.apply_async((1, 2), ignore_result=True)
print(result.get()) # -> None

# Result will be stored
result = mytask.apply_async((1, 2), ignore_result=False)
print(result.get()) # -> 3

By default tasks will *not ignore results* (`ignore_result=False`) when a result backend is configured.

The option precedence order is the following:

1. Global `task_ignore_result`
2. `ignore_result` option
3. Task execution option `ignore_result`

**More optimization tips**

You find additional optimization tips in the *Optimizing Guide*.

**Avoid launching synchronous subtasks**

Having a task wait for the result of another task is really inefficient, and may even cause a deadlock if the worker pool is exhausted.

Make your design asynchronous instead, for example by using *callbacks*.

**Bad:**

```python
@app.task
def update_page_info(url):
    page = fetch_page.delay(url).get()
    info = parse_page.delay(url, page).get()
    store_page_info.delay(url, info)

@app.task
def fetch_page(url):
    return myhttplib.get(url)

@app.task
def parse_page(page):
    returnmyparser.parse_document(page)
```
@app.task
def store_page_info(url, info):
    return PageInfo.objects.create(url, info)

Good:

def update_page_info(url):
    # fetch_page -> parse_page -> store_page
    chain = fetch_page.s(url) | parse_page.s() | store_page_info.s(url)
    chain()

@app.task()
def fetch_page(url):
    return myhttplib.get(url)

@app.task()
def parse_page(page):
    return myparser.parse_document(page)

@app.task(ignore_result=True)
def store_page_info(info, url):
    PageInfo.objects.create(url=url, info=info)

Here I instead created a chain of tasks by linking together different \texttt{signature}()’s. You can read about chains and other powerful constructs at \textit{Canvas: Designing Work-flows}.

By default Celery will not allow you to run subtasks synchronously within a task, but in rare or extreme cases you might need to do so. \textbf{WARNING}: enabling subtasks to run synchronously is not recommended!

@app.task
def update_page_info(url):
    page = fetch_page.delay(url).get(disable_sync_subtasks=False)
    info = parse_page.delay(url, page).get(disable_sync_subtasks=False)
    store_page_info.delay(url, info)

@app.task
def fetch_page(url):
    return myhttplib.get(url)

@app.task
def parse_page(url, page):
    return myparser.parse_document(page)

@app.task
def store_page_info(url, info):
    return PageInfo.objects.create(url, info)

\textbf{Performance and Strategies}

\textbf{Granularity}

The task granularity is the amount of computation needed by each subtask. In general it is better to split the problem up into many small tasks rather than have a few long running tasks.
With smaller tasks you can process more tasks in parallel and the tasks won’t run long enough to block the worker from processing other waiting tasks.

However, executing a task does have overhead. A message needs to be sent, data may not be local, etc. So if the tasks are too fine-grained the overhead added probably removes any benefit.

See also:
The book Art of Concurrency has a section dedicated to the topic of task granularity [AOC1].

Data locality

The worker processing the task should be as close to the data as possible. The best would be to have a copy in memory, the worst would be a full transfer from another continent.

If the data is far away, you could try to run another worker at location, or if that’s not possible - cache often used data, or preload data you know is going to be used.

The easiest way to share data between workers is to use a distributed cache system, like memcached.

See also:
The paper Distributed Computing Economics by Jim Gray is an excellent introduction to the topic of data locality.

State

Since Celery is a distributed system, you can’t know which process, or on what machine the task will be executed. You can’t even know if the task will run in a timely manner.

The ancient async sayings tells us that “asserting the world is the responsibility of the task”. What this means is that the world view may have changed since the task was requested, so the task is responsible for making sure the world is how it should be; If you have a task that re-indexes a search engine, and the search engine should only be re-indexed at maximum every 5 minutes, then it must be the tasks responsibility to assert that, not the callers.

Another gotcha is Django model objects. They shouldn’t be passed on as arguments to tasks. It’s almost always better to re-fetch the object from the database when the task is running instead, as using old data may lead to race conditions.

Imagine the following scenario where you have an article and a task that automatically expands some abbreviations in it:

```python
class Article(models.Model):
    title = models.CharField()
    body = models.TextField()

@app.task
def expand_abbreviations(article):
    article.body.replace('MyCorp', 'My Corporation')
    article.save()
```

First, an author creates an article and saves it, then the author clicks on a button that initiates the abbreviation task:

```python
>>> article = Article.objects.get(id=102)
>>> expand_abbreviations.delay(article)
```

Now, the queue is very busy, so the task won’t be run for another 2 minutes. In the meantime another author makes changes to the article, so when the task is finally run, the body of the article is reverted to the old version because the task had the old body in its argument.

Fixing the race condition is easy, just use the article id instead, and re-fetch the article in the task body:
There might even be performance benefits to this approach, as sending large messages may be expensive.

### Database transactions

Let’s have a look at another example:

```python
from django.db import transaction
from django.http import HttpResponseRedirect

@transaction.atomic
def create_article(request):
    article = Article.objects.create()
    expand_abbreviations.delay(article.pk)
    return HttpResponseRedirect('/articles/)
```

This is a Django view creating an article object in the database, then passing the primary key to a task. It uses the `transaction.atomic` decorator, that will commit the transaction when the view returns, or roll back if the view raises an exception.

There’s a race condition if the task starts executing before the transaction has been committed; The database object doesn’t exist yet!

The solution is to use the `on_commit` callback to launch your Celery task once all transactions have been committed successfully.

```python
from django.db.transaction import on_commit
def create_article(request):
    article = Article.objects.create()
    on_commit(lambda: expand_abbreviations.delay(article.pk))
```

---

**Note:** `on_commit` is available in Django 1.9 and above, if you are using a version prior to that then the `django-transaction-hooks` library adds support for this.

### Example

Let’s take a real world example: a blog where comments posted need to be filtered for spam. When the comment is created, the spam filter runs in the background, so the user doesn’t have to wait for it to finish.

I have a Django blog application allowing comments on blog posts. I’ll describe parts of the models/views and tasks for this application.
Celery Documentation, Release 4.4.0

blog/models.py
The comment model looks like this:
from django.db import models
from django.utils.translation import ugettext_lazy as _

class Comment(models.Model):
name = models.CharField(_('name'), max_length=64)
email_address = models.EmailField(_('email address'))
homepage = models.URLField(_('home page'),
blank=True, verify_exists=False)
comment = models.TextField(_('comment'))
pub_date = models.DateTimeField(_('Published date'),
editable=False, auto_add_now=True)
is_spam = models.BooleanField(_('spam?'),
default=False, editable=False)
class Meta:
verbose_name = _('comment')
verbose_name_plural = _('comments')

In the view where the comment is posted, I first write the comment to the database, then I launch the spam filter task
in the background.
blog/views.py

To make API calls to Akismet I use the akismet.py library written by Michael Foord.

```python
from celery import Celery
from akismet import Akismet
from django.core.exceptions import ImproperlyConfigured
from django.contrib.sites.models import Site
from blog.models import Comment

app = Celery(broker='amqp://')

@app.task
def spam_filter(comment_id, remote_addr=None):
    logger = spam_filter.get_logger()
    logger.info('Running spam filter for comment %s', comment_id)

    comment = Comment.objects.get(pk=comment_id)
    current_domain = Site.objects.get_current().domain
    akismet = Akismet(settings.AKISMET_KEY, 'http://{0}'.format(domain))
    if not akismet.verify_key():
        raise ImproperlyConfigured('Invalid AKISMET_KEY')

    is_spam = akismet.comment_check(user_ip=remote_addr,
                                    comment_content=comment.comment,
                                    comment_author=comment.name,
                                    comment_author_email=comment.email_address)

    if is_spam:
        comment.is_spam = True
        comment.save()

    return is_spam
```

### 3.3.3 Calling Tasks

- **Basics**
### Basics

This document describes Celery’s uniform “Calling API” used by task instances and the `canvas`.

The API defines a standard set of execution options, as well as three methods:

- `apply_async(args[, kwargs[, ...]])`
  
  Sends a task message.

- `delay(*args, **kwargs)`
  
  Shortcut to send a task message, but doesn’t support execution options.

- `calling` (`__call__`)
  
  Applying an object supporting the calling API (e.g., `add(2, 2)`) means that the task will not be executed by a worker, but in the current process instead (a message won’t be sent).

### Quick Cheat Sheet

- **T.delay(arg, kwarg=value)** Star arguments shortcut to `.apply_async` (`.delay(*args, **kwargs)` calls `.apply_async(args, kwargs)`).

- **T.apply_async(countdown=10)** executes in 10 seconds from now.

- **T.apply_async(eta=now + timedelta(seconds=10))** executes in 10 seconds from now, specified using `eta`.

- **T.apply_async(countdown=60, expires=120)** executes in one minute from now, but expires after 2 minutes.

- **T.apply_async(expires=now + timedelta(days=2))** expires in 2 days, set using `datetime`. 

---

- Linking (callbacks/errbacks)
- On message
- ETA and Countdown
- Expiration
- Message Sending Retry
- Connection Error Handling
- Serializers
- Compression
- Connections
- Routing options
- Results options
Example

The `delay()` method is convenient as it looks like calling a regular function:

```python
task.delay(arg1, arg2, kwarg1='x', kwarg2='y')
```

Using `apply_async()` instead you have to write:

```python
task.apply_async(args=[arg1, arg2], kwargs={'kwarg1': 'x', 'kwarg2': 'y'})
```

Tip

If the task isn’t registered in the current process you can use `send_task()` to call the task by name instead.

So `delay` is clearly convenient, but if you want to set additional execution options you have to use `apply_async`. The rest of this document will go into the task execution options in detail. All examples use a task called `add`, returning the sum of two arguments:

```python
@app.task
def add(x, y):
    return x + y
```

There's another way...

You’ll learn more about this later while reading about the `Canvas`, but `signature`s are objects used to pass around the signature of a task invocation, (for example to send it over the network), and they also support the Calling API:

```python
task.s(arg1, arg2, kwarg1='x', kwarg2='y').apply_async()
```

Linking (callbacks/errbacks)

Celery supports linking tasks together so that one task follows another. The callback task will be applied with the result of the parent task as a partial argument:

```python
add.apply_async((2, 2), link=add.s(16))
```

What’s `s`?

The `add.s` call used here is called a signature. If you don’t know what they are you should read about them in the `canvas guide`. There you can also learn about `chain`: a simpler way to chain tasks together.

In practice the `link` execution option is considered an internal primitive, and you’ll probably not use it directly, but use chains instead.

Here the result of the first task (4) will be sent to a new task that adds 16 to the previous result, forming the expression 

\[(2 + 2) + 16 = 20\]

You can also cause a callback to be applied if task raises an exception (`errback`), but this behaves differently from a regular callback in that it will be passed the id of the parent task, not the result. This is because it may not always be
possible to serialize the exception raised, and so this way the error callback requires a result backend to be enabled, and the task must retrieve the result of the task instead.

This is an example error callback:

```python
@app.task
def error_handler(uuid):
    result =AsyncResult(uuid)
    exc = result.get(propagate=False)
    print('Task {0} raised exception: {1!r}
       {2!r}'.format(
        uuid, exc, result.traceback))
```

it can be added to the task using the `link_error` execution option:

```python
add.apply_async((2, 2), link_error=error_handler.s())
```

In addition, both the `link` and `link_error` options can be expressed as a list:

```python
add.apply_async((2, 2), link=[add.s(16), other_task.s()])
```

The callbacks/errbacks will then be called in order, and all callbacks will be called with the return value of the parent task as a partial argument.

### On message

Celery supports catching all states changes by setting on_message callback. For example for long-running tasks to send task progress you can do something like this:

```python
@app.task(bind=True)
def hello(self, a, b):
    time.sleep(1)
    self.update_state(state="PROGRESS", meta={"progress": 50})
    time.sleep(1)
    self.update_state(state="PROGRESS", meta={"progress": 90})
    time.sleep(1)
    return 'hello world: %i % (a+b)

def on_raw_message(body):
    print(body)
    a, b = 1, 1
    r = hello.apply_async(args=(a, b))
    print(r.get(on_message=on_raw_message, propagate=False))
```

Will generate output like this:

```json
{'task_id': '5660d3a3-92b8-40df-8ccc-33a5d1d680d7',
 'result': {'progress': 50},
 'children': [],
 'status': 'PROGRESS',
 'traceback': None}
{'task_id': '5660d3a3-92b8-40df-8ccc-33a5d1d680d7',
 'result': {'progress': 90},
 'children': [],
 'status': 'PROGRESS',
 'traceback': None}
```

(continues on next page)
ETA and Countdown

The ETA (estimated time of arrival) lets you set a specific date and time that is the earliest time at which your task will be executed. `countdown` is a shortcut to set ETA by seconds into the future.

```python
>>> result = add.apply_async((2, 2), countdown=3)
>>> result.get()  # this takes at least 3 seconds to return
20
```

The task is guaranteed to be executed at some time after the specified date and time, but not necessarily at that exact time. Possible reasons for broken deadlines may include many items waiting in the queue, or heavy network latency. To make sure your tasks are executed in a timely manner you should monitor the queue for congestion. Use Munin, or similar tools, to receive alerts, so appropriate action can be taken to ease the workload. See `Munin`.

While `countdown` is an integer, `eta` must be a `datetime` object, specifying an exact date and time (including millisecond precision, and timezone information):

```python
>>> from datetime import datetime, timedelta

>>> tomorrow = datetime.utcnow() + timedelta(days=1)
>>> add.apply_async((2, 2), eta=tomorrow)
```

Expiration

The `expires` argument defines an optional expiry time, either as seconds after task publish, or a specific date and time using `datetime`:

```python
>>> # Task expires after one minute from now.
>>> add.apply_async((10, 10), expires=60)

>>> # Also supports datetime
>>> from datetime import datetime, timedelta

>>> add.apply_async((10, 10), kwargs,
...                 expires=datetime.now() + timedelta(days=1))
```

When a worker receives an expired task it will mark the task as `REVOKED(TaskRevokedError)`.

Message Sending Retry

Celery will automatically retry sending messages in the event of connection failure, and retry behavior can be configured – like how often to retry, or a maximum number of retries – or disabled all together.

To disable retry you can set the `retry` execution option to `False`:

```python
add.apply_async((2, 2), retry=False)
```
Related Settings

- `task_publish_retry`
- `task_publish_retry_policy`

Retry Policy

A retry policy is a mapping that controls how retries behave, and can contain the following keys:

- `max_retries`
  - Maximum number of retries before giving up, in this case the exception that caused the retry to fail will be raised.
  - A value of `None` means it will retry forever.
  - The default is to retry 3 times.

- `interval_start`
  - Defines the number of seconds (float or integer) to wait between retries. Default is 0 (the first retry will be instantaneous).

- `interval_step`
  - On each consecutive retry this number will be added to the retry delay (float or integer). Default is 0.2.

- `interval_max`
  - Maximum number of seconds (float or integer) to wait between retries. Default is 0.2.

For example, the default policy correlates to:

```python
add.apply_async((2, 2), retry=True, retry_policy={
    'max_retries': 3,
    'interval_start': 0,
    'interval_step': 0.2,
    'interval_max': 0.2,
})
```

the maximum time spent retrying will be 0.4 seconds. It’s set relatively short by default because a connection failure could lead to a retry pile effect if the broker connection is down – For example, many web server processes waiting to retry, blocking other incoming requests.

Connection Error Handling

When you send a task and the message transport connection is lost, or the connection cannot be initiated, an `OperationalError` error will be raised:

```python
>>> from proj.tasks import add
>>> add.delay(2, 2)
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
  File "celery/app/task.py", line 388, in delay
    return self.apply_async(args, kwargs)
```

(continues on next page)
...
Binary data will be transferred using Base64 encoding, increasing the size of the transferred data by 34% compared to an encoding format where native binary types are supported.

However, if your data fits inside the above constraints and you need cross-language support, the default setting of JSON is probably your best choice.

See http://json.org for more information.

**pickle** – If you have no desire to support any language other than Python, then using the pickle encoding will gain you the support of all built-in Python data types (except class instances), smaller messages when sending binary files, and a slight speedup over JSON processing.

See pickle for more information.

**yaml** – YAML has many of the same characteristics as json, except that it natively supports more data types (including dates, recursive references, etc.).

However, the Python libraries for YAML are a good bit slower than the libraries for JSON.

If you need a more expressive set of data types and need to maintain cross-language compatibility, then YAML may be a better fit than the above.

See http://yaml.org/ for more information.

**msgpack** – msgpack is a binary serialization format that’s closer to JSON in features. It’s very young however, and support should be considered experimental at this point.

See http://msgpack.org/ for more information.

The encoding used is available as a message header, so the worker knows how to deserialize any task. If you use a custom serializer, this serializer must be available for the worker.

The following order is used to decide the serializer used when sending a task:

1. The `serializer` execution option.
2. The `Task.serializer` attribute
3. The `task_serializer` setting.

Example setting a custom serializer for a single task invocation:

```python
>>> add.apply_async((10, 10), serializer='json')
```

**Compression**

Celery can compress messages using the following builtin schemes:

- **brotli**

  brotli is optimized for the web, in particular small text documents. It is most effective for serving static content such as fonts and html pages.

  To use it, install Celery with:

  ```bash
  $ pip install celery[brotli]
  ```

- **bzip2**

  bzip2 creates smaller files than gzip, but compression and decompression speeds are noticeably slower than those of gzip.

  To use it, please ensure your Python executable was compiled with bzip2 support.
If you get the following `ImportError`:

```python
>>> import bz2
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
ImportError: No module named 'bz2'
```

it means that you should recompile your Python version with bzip2 support.

- **gzip**

  gzip is suitable for systems that require a small memory footprint, making it ideal for systems with limited memory. It is often used to generate files with the "`.tar.gz`" extension.

  To use it, please ensure your Python executable was compiled with gzip support.

  If you get the following `ImportError`:

  ```python
  >>> import gzip
  Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
  ImportError: No module named 'gzip'
  ```

  it means that you should recompile your Python version with gzip support.

- **lzma**

  Lzma provides a good compression ratio and executes with fast compression and decompression speeds at the expense of higher memory usage.

  To use it, please ensure your Python executable was compiled with lzma support and that your Python version is 3.3 and above.

  If you get the following `ImportError`:

  ```python
  >>> import lzma
  Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
  ImportError: No module named 'lzma'
  ```

  it means that you should recompile your Python version with lzma support.

  Alternatively, you can also install a backport using:

  ```bash
  $ pip install celery[lzma]
  ```

- **zlib**

  Zlib is an abstraction of the Deflate algorithm in library form which includes support both for the gzip file format and a lightweight stream format in its API. It is a crucial component of many software systems - Linux kernel and Git VCS just to name a few.

  To use it, please ensure your Python executable was compiled with zlib support.

  If you get the following `ImportError`:

  ```python
  >>> import zlib
  Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
  ImportError: No module named 'zlib'
  ```

  it means that you should recompile your Python version with zlib support.
• **zstd**

  zstd targets real-time compression scenarios at zlib-level and better compression ratios. It’s backed by a very fast entropy stage, provided by Huff0 and FSE library.

  To use it, install Celery with:

  ```
  $ pip install celery[zstd]
  ```

  You can also create your own compression schemes and register them in the kombu compression registry.

  The following order is used to decide the compression scheme used when sending a task:

  1. The `compression` execution option.
  2. The `Task.compression` attribute.
  3. The `task_compression` attribute.

  Example specifying the compression used when calling a task:

  ```python
  >>> add.apply_async((2, 2), compression='zlib')
  ```

### Connections

#### Automatic Pool Support

Since version 2.3 there’s support for automatic connection pools, so you don’t have to manually handle connections and publishers to reuse connections.

The connection pool is enabled by default since version 2.5.

See the `broker_pool_limit` setting for more information.

You can handle the connection manually by creating a publisher:

```python
results = []
with add.app.pool.acquire(block=True) as connection:
    with add.get_publisher(connection) as publisher:
        try:
            for args in numbers:
                res = add.apply_async((2, 2), publisher=publisher)
                results.append(res)
        print([res.get() for res in results])
```

Though this particular example is much better expressed as a group:

```python
>>> from celery import group
>>> numbers = [(2, 2), (4, 4), (8, 8), (16, 16)]
>>> res = group(add.s(i, j) for i, j in numbers).apply_async()
>>> res.get()
[4, 8, 16, 32]
```
Routing options

Celery can route tasks to different queues.
Simple routing (name <-> name) is accomplished using the queue option:

```python
add.apply_async(queue='priority.high')
```

You can then assign workers to the `priority.high` queue by using the workers `-Q` argument:

```
$ celery -A proj worker -l info -Q celery,priority.high
```

See also:

Hard-coding queue names in code isn’t recommended, the best practice is to use configuration routers (`task_routes`).
To find out more about routing, please see *Routing Tasks*.

Results options

You can enable or disable result storage using the `task_ignore_result` setting or by using the `ignore_result` option:

```python
>>> result = add.apply_async(1, 2, ignore_result=True)
>>> result.get()
None

>>> # Do not ignore result (default)
... >>> result = add.apply_async(1, 2, ignore_result=False)
>>> result.get()
3
```

If you’d like to store additional metadata about the task in the result backend set the `result_extended` setting to `True`.

See also:

For more information on tasks, please see *Tasks*.

Advanced Options

These options are for advanced users who want to take use of AMQP’s full routing capabilities. Interested parties may read the *routing guide*.

- exchange
  
  Name of exchange (or a `kombu.entity.Exchange`) to send the message to.

- routing_key
  
  Routing key used to determine.

- priority
  
  A number between 0 and 255, where 255 is the highest priority.
  
  Supported by: RabbitMQ, Redis (priority reversed, 0 is highest).

  - Chunks

## Signatures

New in version 2.0.

You just learned how to call a task using the tasks `delay` method in the *calling* guide, and this is often all you need, but sometimes you may want to pass the signature of a task invocation to another process or as an argument to another function.

A `signature()` wraps the arguments, keyword arguments, and execution options of a single task invocation in a way such that it can be passed to functions or even serialized and sent across the wire.

- You can create a signature for the `add` task using its name like this:

  ```python
  >>> from celery import signature
  >>> signature('tasks.add', args=(2, 2), countdown=10)
  tasks.add(2, 2)
  ```

  This task has a signature of arity 2 (two arguments): `(2, 2)`, and sets the countdown execution option to 10.

- or you can create one using the task’s `signature` method:

  ```python
  >>> add.signature((2, 2), countdown=10)
  tasks.add(2, 2)
  ```

- There’s also a shortcut using star arguments:

  ```python
  >>> add.s(2, 2)
  tasks.add(2, 2)
  ```

- Keyword arguments are also supported:

  ```python
  >>> add.s(2, 2, debug=True)
  tasks.add(2, 2, debug=True)
  ```

- From any signature instance you can inspect the different fields:
• It supports the “Calling API” of `delay`, `apply_async`, etc., including being called directly (`__call__`).

Calling the signature will execute the task inline in the current process:

```python
>>> add(2, 2)
4
>>> add.s(2, 2)()
4
```
delay is our beloved shortcut to `apply_async` taking star-arguments:

```python
>>> result = add.delay(2, 2)
>>> result.get()
4
```

`apply_async` takes the same arguments as the `app.Task.apply_async()` method:

```python
>>> add.apply_async(args, kwars, **options)
>>> add.signature(args, kwars, **options).apply_async()
>>> add.apply_async((2, 2), countdown=1)
>>> add.signature((2, 2), countdown=1).apply_async()
```

• You can’t define options with `s()`, but a chaining `set` call takes care of that:

```python
>>> add.s(2, 2).set(countdown=1)
proj.tasks.add(2, 2)
```

### Partials

With a signature, you can execute the task in a worker:

```python
>>> add.s(2, 2).delay()
>>> add.s(2, 2).apply_async(countdown=1)
```

Or you can call it directly in the current process:

```python
>>> add.s(2, 2)()
```

Specifying additional args, kwars, or options to `apply_async/delay` creates partials:

• Any arguments added will be prepended to the args in the signature:

```python
>>> partial = add.s(2) # incomplete signature
>>> partial.delay(4)  # 4 + 2
>>> partial.apply_async((4,)) # same
```
• Any keyword arguments added will be merged with the kwargs in the signature, with the new keyword arguments taking precedence:

```python
>>> s = add.s(2, 2)
>>> s.delay(debug=True)  # -> add(2, 2, debug=True)
>>> s.apply_async(kwargs={'debug': True})  # same
```

• Any options added will be merged with the options in the signature, with the new options taking precedence:

```python
>>> s = add.signature((2, 2), countdown=10)
>>> s.apply_async(countdown=1)  # countdown is now 1
```

You can also clone signatures to create derivatives:

```python
>>> s = add.s(2)
proj.tasks.add(2)

>>> s.clone(args=(4,), kwargs={'debug': True})
proj.tasks.add(4, 2, debug=True)
```

### Immutability

New in version 3.0.

Partials are meant to be used with callbacks, any tasks linked, or chord callbacks will be applied with the result of the parent task. Sometimes you want to specify a callback that doesn’t take additional arguments, and in that case you can set the signature to be immutable:

```python
>>> add.apply_async((2, 2), link=reset_buffers.signature(immutable=True))
```

The `.si()` shortcut can also be used to create immutable signatures:

```python
>>> add.apply_async((2, 2), link=reset_buffers.si())
```

Only the execution options can be set when a signature is immutable, so it’s not possible to call the signature with partial args/kwargs.

**Note:** In this tutorial I sometimes use the prefix operator ~ to signatures. You probably shouldn’t use it in your production code, but it’s a handy shortcut when experimenting in the Python shell:

```python
>>> ~sig
>>> # is the same as
>>> sig.delay().get()
```

### Callbacks

New in version 3.0.

Callbacks can be added to any task using the `link` argument to `apply_async`:

```python
add.apply_async((2, 2), link=other_task.s())
```
The callback will only be applied if the task exited successfully, and it will be applied with the return value of the parent task as argument.

As I mentioned earlier, any arguments you add to a signature, will be prepended to the arguments specified by the signature itself!

If you have the signature:

```python
>>> sig = add.s(10)
```

then `sig.delay(result)` becomes:

```python
>>> add.apply_async(args=(result, 10))
```

... 

Now let’s call our `add` task with a callback using partial arguments:

```python
>>> add.apply_async((2, 2), link=add.s(8))
```

As expected this will first launch one task calculating $2 + 2$, then another task calculating $4 + 8$.

**The Primitives**

New in version 3.0.

**Overview**

- **group**
  The group primitive is a signature that takes a list of tasks that should be applied in parallel.

- **chain**
  The chain primitive lets us link together signatures so that one is called after the other, essentially forming a chain of callbacks.

- **chord**
  A chord is just like a group but with a callback. A chord consists of a header group and a body, where the body is a task that should execute after all of the tasks in the header are complete.

- **map**
  The map primitive works like the built-in `map` function, but creates a temporary task where a list of arguments is applied to the task. For example, `task.map([1, 2])` – results in a single task being called, applying the arguments in order to the task function so that the result is:

```python
res = [task(1), task(2)]
```

- **starmap**
  Works exactly like map except the arguments are applied as `*args`. For example `add.starmap([(2, 2), (4, 4)])` results in a single task calling:

```python
res = [add(2, 2), add(4, 4)]
```

- **chunks**
  Chunking splits a long list of arguments into parts, for example the operation:
The primitives are also signature objects themselves, so that they can be combined in any number of ways to compose complex work-flows.

Here’s some examples:

- **Simple chain**

  Here’s a simple chain, the first task executes passing its return value to the next task in the chain, and so on.

  ```python
  >>> from celery import chain
  >>> # 2 + 2 + 4 + 8
  >>> res = chain(add.s(2, 2), add.s(4), add.s(8))()
  >>> res.get()
  16
  ```

  This can also be written using pipes:

  ```python
  >>> (add.s(2, 2) | add.s(4) | add.s(8)).get()
  16
  ```

- **Immutable signatures**

  Signatures can be partial so arguments can be added to the existing arguments, but you may not always want that, for example if you don’t want the result of the previous task in a chain.

  In that case you can mark the signature as immutable, so that the arguments cannot be changed:

  ```python
  >>> add.signature((2, 2), immutable=True)
  ```

  There’s also a .si() shortcut for this, and this is the preferred way of creating signatures:

  ```python
  >>> add.si(2, 2)
  ```

  Now you can create a chain of independent tasks instead:

  ```python
  >>> res = (add.si(2, 2) | add.si(4, 4) | add.si(8, 8))()
  >>> res.get()
  16
  >>> res.parent.get()
  8
  >>> res.parent.parent.get()
  4
  ```

- **Simple group**

  You can easily create a group of tasks to execute in parallel:
>>> from celery import group
>>> res = group(add.s(i, i) for i in xrange(10))()
[0, 2, 4, 6, 8, 10, 12, 14, 16, 18]

• Simple chord

The chord primitive enables us to add a callback to be called when all of the tasks in a group have
finished executing. This is often required for algorithms that aren’t embarrassingly parallel:

>>> from celery import chord
>>> res = chord((add.s(i, i) for i in xrange(10)), xsum.s)()  # xsum
90

The above example creates 10 task that all start in parallel, and when all of them are complete the
return values are combined into a list and sent to the xsum task.

The body of a chord can also be immutable, so that the return value of the group isn’t passed on to
the callback:

>>> chord((import_contact.s(c) for c in contacts), ...
...          notify_complete.si(import_id)).apply_async()

Note the use of .si above; this creates an immutable signature, meaning any new arguments passed
(including to return value of the previous task) will be ignored.

• Blow your mind by combining

Chains can be partial too:

```python
>>> c1 = (add.s(4) | mul.s(8))  # (16 + 4) * 8
>>> res = c1(16)
>>> res.get()
160
```

this means that you can combine chains:

```python
# ((4 + 16) * 2 + 4) * 8
>>> c2 = (add.s(4, 16) | mul.s(2) | (add.s(4) | mul.s(8)))
```

```python
>>> res = c2()
>>> res.get()
352
```

Chaining a group together with another task will automatically upgrade it to be a chord:

```python
>>> c3 = (group(add.s(i, i) for i in xrange(10)) | xsum.s())
>>> res = c3()
>>> res.get()
90
```

Groups and chords accepts partial arguments too, so in a chain the return value of the previous task
is forwarded to all tasks in the group:
new_user_workflow = (create_user.s() | group(
    ... import_contacts.s(),
    ... send_welcome_email.s()))

new_user_workflow.delay(username='artv',
    ... first='Art',
    ... last='Vandelay',
    ... email='art@vandelay.com')

If you don’t want to forward arguments to the group then you can make the signatures in the group immutuable:

res = (add.s(4, 4) | group(add.si(i, i) for i in xrange(10)))(
res.get()

Chains

New in version 3.0.

Tasks can be linked together: the linked task is called when the task returns successfully:

res = add.apply_async((2, 2), link=mul.s(16))
res.get()

The linked task will be applied with the result of its parent task as the first argument. In the above case where the result was 4, this will result in mul(4, 16).

The results will keep track of any subtasks called by the original task, and this can be accessed from the result instance:

res.children
[<AsyncResult: 8c350acf-519d-4553-8a53-4ad3a5c5aeb4>]
res.children[0].get()

The result instance also has a collect() method that treats the result as a graph, enabling you to iterate over the results:

list(res.collect())
[(<AsyncResult: 7b720856-dc5f-4415-9134-5c89def5664e>, 4),
 (<AsyncResult: 8c350acf-519d-4553-8a53-4ad3a5c5aeb4>, 64)]
By default `collect()` will raise an `IncompleteStream` exception if the graph isn’t fully formed (one of the tasks hasn’t completed yet), but you can get an intermediate representation of the graph too:

```python
>>> for result, value in res.collect(intermediate=True):
....
```

You can link together as many tasks as you like, and signatures can be linked too:

```python
>>> s = add.s(2, 2)
>>> s.link(mul.s(4))
>>> s.link(log_result.s())
```

You can also add *error callbacks* using the `on_error` method:

```python
>>> add.s(2, 2).on_error(log_error.s().delay())
```

This will result in the following `.apply_async` call when the signature is applied:

```python
>>> add.apply_async((2, 2), link_error=log_error.s())
```

The worker won’t actually call the errback as a task, but will instead call the errback function directly so that the raw request, exception and traceback objects can be passed to it.

Here’s an example errback:

```python
from __future__ import print_function
import os
from proj.celery import app

@app.task
def log_error(request, exc, traceback):
    with open(os.path.join('/var/errors', request.id), 'a') as fh:
        print('--
{0} {1} {2}'.format(task_id, exc, traceback), file=fh)
```

To make it even easier to link tasks together there’s a special signature called `chain` that lets you chain tasks together:

```python
>>> from celery import chain
>>> from proj.tasks import add, mul

>>> # (4 + 4) * 8 * 10
>>> res = chain(add.s(4, 4), mul.s(8), mul.s(10))
proj.tasks.add(4, 4) | proj.tasks.mul(8) | proj.tasks.mul(10)
```

Calling the chain will call the tasks in the current process and return the result of the last task in the chain:

```python
>>> res = chain(add.s(4, 4), mul.s(8), mul.s(10))()
>>> res.get()
640
```

It also sets `parent` attributes so that you can work your way up the chain to get intermediate results:

```python
>>> res.parent.get()
64
>>> res.parent.parent.get()
```

(continues on next page)
Chains can also be made using the | (pipe) operator:

```python
>>> (add.s(2, 2) | mul.s(8) | mul.s(10)).apply_async()
```

**Graphs**

In addition you can work with the result graph as a `DependencyGraph`:

```python
>>> res = chain(add.s(4, 4), mul.s(8), mul.s(10))()

>>> res.parent.parent.graph
```

You can even convert these graphs to *dot* format:

```python
>>> with open('graph.dot', 'w') as fh:
...     res.parent.parent.graph.to_dot(fh)
```

and create images:

```
$ dot -Tpng graph.dot -o graph.png
```

![Graph Diagram](image-url)
Groups

New in version 3.0.

A group can be used to execute several tasks in parallel.

The `group` function takes a list of signatures:

```python
>>> from celery import group
>>> from proj.tasks import add

>>> group(add.s(2, 2), add.s(4, 4))
(proj.tasks.add(2, 2), proj.tasks.add(4, 4))
```

If you call the group, the tasks will be applied one after another in the current process, and a `GroupResult` instance is returned that can be used to keep track of the results, or tell how many tasks are ready and so on:

```python
>>> g = group(add.s(2, 2), add.s(4, 4))
>>> res = g()
>>> res.get()
[4, 8]
```

Group also supports iterators:

```python
>>> group(add.s(i, i) for i in xrange(100))()
```

A group is a signature object, so it can be used in combination with other signatures.

Group Results

The group task returns a special result too, this result works just like normal task results, except that it works on the group as a whole:

```python
>>> from celery import group
>>> from tasks import add

>>> job = group([
...    add.s(2, 2),
...    add.s(4, 4),
...    add.s(8, 8),
...    add.s(16, 16),
...    add.s(32, 32),
...])

>>> result = job.apply_async()

>>> result.ready()  # have all subtasks completed?
True

>>> result.successful()  # were all subtasks successful?
True

>>> result.get()
[4, 8, 16, 32, 64]
```

The `GroupResult` takes a list of `AsyncResult` instances and operates on them as if it was a single task.

It supports the following operations:

- `successful()`
Return True if all of the subtasks finished successfully (e.g., didn’t raise an exception).

- failed()
  Return True if any of the subtasks failed.

- waiting()
  Return True if any of the subtasks isn’t ready yet.

- ready()
  Return True if all of the subtasks are ready.

- completed_count()
  Return the number of completed subtasks.

- revoke()
  Revoke all of the subtasks.

- join()
  Gather the results of all subtasks and return them in the same order as they were called (as a list).

### Chords

New in version 2.3.

**Note:** Tasks used within a chord must not ignore their results. If the result backend is disabled for any task (header or body) in your chord you should read “Important Notes.” Chords are not currently supported with the RPC result backend.

A chord is a task that only executes after all of the tasks in a group have finished executing.

Let’s calculate the sum of the expression $1 + 1 + 2 + 2 + 3 + 3 + \ldots + n + n$ up to a hundred digits.

First you need two tasks, `add()` and `tsum()` (`sum()` is already a standard function):

```python
@app.task
def add(x, y):
    return x + y

@app.task
def tsum(numbers):
    return sum(numbers)
```

Now you can use a chord to calculate each addition step in parallel, and then get the sum of the resulting numbers:

```python
>>> from celery import chord
>>> from tasks import add, tsum

>>> chord(add.s(i, i) for i in xrange(100))(tsum.s()).get()
9900
```

This is obviously a very contrived example, the overhead of messaging and synchronization makes this a lot slower than its Python counterpart:
The synchronization step is costly, so you should avoid using chords as much as possible. Still, the chord is a powerful primitive to have in your toolbox as synchronization is a required step for many parallel algorithms.

Let’s break the chord expression down:

```python
>>> callback = tsum.s()
>>> header = [add.s(i, i) for i in range(100)]
>>> result = chord(header)(callback)
>>> result.get()
9900
```

Remember, the callback can only be executed after all of the tasks in the header have returned. Each step in the header is executed as a task, in parallel, possibly on different nodes. The callback is then applied with the return value of each task in the header. The task id returned by `chord()` is the id of the callback, so you can wait for it to complete and get the final return value (but remember to never have a task wait for other tasks)

### Error handling

So what happens if one of the tasks raises an exception?

The chord callback result will transition to the failure state, and the error is set to the `ChordError` exception:

```python
>>> c = chord([add.s(4, 4), raising_task.s(), add.s(8, 8)])
>>> result = c()
>>> result.get()
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
  File "*/celery/result.py", line 120, in get
    interval=interval)
  File "*/celery/backends/amqp.py", line 150, in wait_for
    raise meta['result']['celery.exceptions.ChordError: Dependency 97de6f3f-ea67-4517-a21c-d867c61fcb47 raised ValueError('something something',)
```

While the traceback may be different depending on the result backend used, you can see that the error description includes the id of the task that failed and a string representation of the original exception. You can also find the original traceback in `result.traceback`.

Note that the rest of the tasks will still execute, so the third task (`add.s(8, 8)`) is still executed even though the middle task failed. Also the `ChordError` only shows the task that failed first (in time): it doesn’t respect the ordering of the header group.

To perform an action when a chord fails you can therefore attach an errback to the chord callback:

```python
@app.task
def on_chord_error(request, exc, traceback):
    print('Task {0!r} raised error: {1!r}'.format(request.id, exc))
```

```python
>>> c = (group(add.s(i, i) for i in range(10)) | ...
  xsum.s().on_error(on_chord_error.s())).delay()
```
Important Notes

Tasks used within a chord must not ignore their results. In practice this means that you must enable a `result_backend` in order to use chords. Additionally, if `task_ignore_result` is set to `True` in your configuration, be sure that the individual tasks to be used within the chord are defined with `ignore_result=False`. This applies to both Task subclasses and decorated tasks.

Example Task subclass:

```python
class MyTask(Task):
    ignore_result = False
```

Example decorated task:

```python
@app.task(ignore_result=False)
def another_task(project):
    do_something()
```

By default the synchronization step is implemented by having a recurring task poll the completion of the group every second, calling the signature when ready.

Example implementation:

```python
from celery import maybe_signature

@app.task(bind=True)
def unlock_chord(self, group, callback, interval=1, max_retries=None):
    if group.ready():
        return maybe_signature(callback).delay(group.join())
    raise self.retry(countdown=interval, max_retries=max_retries)
```

This is used by all result backends except Redis and Memcached: they increment a counter after each task in the header, then applies the callback when the counter exceeds the number of tasks in the set.

The Redis and Memcached approach is a much better solution, but not easily implemented in other backends (suggestions welcome!).

**Note:** Chords don’t properly work with Redis before version 2.2; you’ll need to upgrade to at least redis-server 2.2 to use them.

**Note:** If you’re using chords with the Redis result backend and also overriding the `Task.after_return()` method, you need to make sure to call the super method or else the chord callback won’t be applied.

```python
def after_return(self, *args, **kwargs):
    do_something()
    super(MyTask, self).after_return(*args, **kwargs)
```

Map & Starmap

`map` and `starmap` are built-in tasks that calls the task for every element in a sequence.

They differ from group in that
- only one task message is sent
• the operation is sequential.

For example using map:

```
>>> from proj.tasks import add
>>> xsum.map([range(10), range(100)])
[45, 4950]
```

is the same as having a task doing:

```
@app.task
def temp():
    return [xsum(range(10)), xsum(range(100))]
```

and using starmap:

```
>>> add.starmap(zip(range(10), range(10)))
[0, 2, 4, 6, 8, 10, 12, 14, 16, 18]
```

is the same as having a task doing:

```
@app.task
def temp():
    return [add(i, i) for i in range(10)]
```

Both map and starmap are signature objects, so they can be used as other signatures and combined in groups etc., for example to call the starmap after 10 seconds:

```
>>> add.starmap(zip(range(10), range(10))).apply_async(countdown=10)
```

### Chunks

Chunking lets you divide an iterable of work into pieces, so that if you have one million objects, you can create 10 tasks with hundred thousand objects each.

Some may worry that chunking your tasks results in a degradation of parallelism, but this is rarely true for a busy cluster and in practice since you’re avoiding the overhead of messaging it may considerably increase performance.

To create a chunks signature you can use `app.Task.chunks()`:

```
>>> add.chunks(zip(range(100), range(100)), 10)
```

As with `group` the act of sending the messages for the chunks will happen in the current process when called:

```
>>> from proj.tasks import add
>>> res = add.chunks(zip(range(100), range(100)), 10)()
>>> res.get()
[[0, 2, 4, 6, 8, 10, 12, 14, 16, 18],
 [20, 22, 24, 26, 28, 30, 32, 34, 36, 38],
 [40, 42, 44, 46, 48, 50, 52, 54, 56, 58],
 [60, 62, 64, 66, 68, 70, 72, 74, 76, 78],
 [80, 82, 84, 86, 88, 90, 92, 94, 96, 98],
 [100, 102, 104, 106, 108, 110, 112, 114, 116, 118],
 [120, 122, 124, 126, 128, 130, 132, 134, 136, 138],
 [140, 142, 144, 146, 148, 150, 152, 154, 156, 158],
 ...]
```
while calling `apply_async` will create a dedicated task so that the individual tasks are applied in a worker instead:

```python
>>> add.chunks(zip(range(100), range(100)), 10).apply_async()
```

You can also convert chunks to a group:

```python
>>> group = add.chunks(zip(range(100), range(100)), 10).group()
```

and with the group skew the countdown of each task by increments of one:

```python
>>> group.skew(start=1, stop=10)()
```

This means that the first task will have a countdown of one second, the second task a countdown of two seconds, and so on.

### 3.3.5 Workers Guide

- Starting the worker
- Stopping the worker
- Restarting the worker
- Process Signals
- Variables in file paths
- Concurrency
- Remote control
- Commands
- Time Limits
- Rate Limits
- Max tasks per child setting
- Max memory per child setting
- Autoscaling
- Queues
- Inspecting workers
- Additional Commands
- Writing your own remote control commands

**Starting the worker**
Daemonizing

You probably want to use a daemonization tool to start the worker in the background. See *Daemonization* for help starting the worker as a daemon using popular service managers.

You can start the worker in the foreground by executing the command:

```
$ celery -A proj worker -l info
```

For a full list of available command-line options see *worker*, or simply do:

```
$ celery worker --help
```

You can start multiple workers on the same machine, but be sure to name each individual worker by specifying a node name with the `--hostname` argument:

```
$ celery -A proj worker --loglevel=INFO --concurrency=10 -n worker1@%h
$ celery -A proj worker --loglevel=INFO --concurrency=10 -n worker2@%h
$ celery -A proj worker --loglevel=INFO --concurrency=10 -n worker3@%h
```

The `hostname` argument can expand the following variables:

- `%h`: Hostname, including domain name.
- `%n`: Hostname only.
- `%d`: Domain name only.

If the current hostname is `george.example.com`, these will expand to:

<table>
<thead>
<tr>
<th>Variable</th>
<th>Template</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>%h</code></td>
<td>worker1@%h</td>
<td><code>worker1@george.example.com</code></td>
</tr>
<tr>
<td><code>%n</code></td>
<td>worker1@%n</td>
<td><code>worker1@george</code></td>
</tr>
<tr>
<td><code>%d</code></td>
<td>worker1@%d</td>
<td><code>worker1@example.com</code></td>
</tr>
</tbody>
</table>

**Note for supervisor users**

The `%` sign must be escaped by adding a second one: `%%h`.

Stopping the worker

Shutdown should be accomplished using the `TERM` signal.

When shutdown is initiated the worker will finish all currently executing tasks before it actually terminates. If these tasks are important, you should wait for it to finish before doing anything drastic, like sending the `KILL` signal.

If the worker won’t shutdown after considerate time, for being stuck in an infinite-loop or similar, you can use the `KILL` signal to force terminate the worker: but be aware that currently executing tasks will be lost (i.e., unless the tasks have the `acks_late` option set).

Also as processes can’t override the `KILL` signal, the worker will not be able to reap its children; make sure to do so manually. This command usually does the trick:

```
$ pkill -9 -f 'celery worker'
```
If you don’t have the `pkill` command on your system, you can use the slightly longer version:

```
$ ps auxww | awk '/celery worker/ {print $2}' | xargs kill -9
```

### Restarting the worker

To restart the worker you should send the `TERM` signal and start a new instance. The easiest way to manage workers for development is by using `celery multi`:

```
$ celery multi start 1 -A proj -l info -c4 --pidfile=/var/run/celery/%n.pid
$ celery multi restart 1 --pidfile=/var/run/celery/%n.pid
```

For production deployments you should be using init-scripts or a process supervision system (see `Daemonization`).

Other than stopping, then starting the worker to restart, you can also restart the worker using the `HUP` signal. Note that the worker will be responsible for restarting itself so this is prone to problems and isn’t recommended in production:

```
$ kill -HUP $pid
```

**Note:** Restarting by `HUP` only works if the worker is running in the background as a daemon (it doesn’t have a controlling terminal). `HUP` is disabled on macOS because of a limitation on that platform.

### Process Signals

The worker’s main process overrides the following signals:

<table>
<thead>
<tr>
<th>Signal</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>TERM</code></td>
<td>Warm shutdown, wait for tasks to complete.</td>
</tr>
<tr>
<td><code>QUIT</code></td>
<td>Cold shutdown, terminate ASAP</td>
</tr>
<tr>
<td><code>USR1</code></td>
<td>Dump traceback for all active threads.</td>
</tr>
<tr>
<td><code>USR2</code></td>
<td>Remote debug, see <code>celery.contrib.rdb</code>.</td>
</tr>
</tbody>
</table>

### Variables in file paths

The file path arguments for `--logfile`, `--pidfile`, and `--statedb` can contain variables that the worker will expand:

#### Node name replacements

- `%p`: Full node name.
- `%h`: Hostname, including domain name.
- `%n`: Hostname only.
- `%d`: Domain name only.
- `%i`: Prefork pool process index or 0 if MainProcess.
- `%I`: Prefork pool process index with separator.

For example, if the current hostname is `george@foo.example.com` then these will expand to:
Prefork pool process index

The prefork pool process index specifiers will expand into a different filename depending on the process that’ll eventually need to open the file.

This can be used to specify one log file per child process.

Note that the numbers will stay within the process limit even if processes exit or if autoscale/maxtasksperchild/time limits are used. That is, the number is the process index not the process count or pid.

- %i - Pool process index or 0 if MainProcess.
  Where -n worker1@example.com -c2 -f %n-%i.log will result in three log files:
  - worker1-0.log (main process)
  - worker1-1.log (pool process 1)
  - worker1-2.log (pool process 2)

- %I - Pool process index with separator.
  Where -n worker1@example.com -c2 -f %n%I.log will result in three log files:
  - worker1.log (main process)
  - worker1-1.log (pool process 1)
  - worker1-2.log (pool process 2)

Concurrency

By default multiprocessing is used to perform concurrent execution of tasks, but you can also use Eventlet. The number of worker processes/threads can be changed using the --concurrency argument and defaults to the number of CPUs available on the machine.

Number of processes (multiprocessing/prefork pool)

More pool processes are usually better, but there’s a cut-off point where adding more pool processes affects performance in negative ways. There’s even some evidence to support that having multiple worker instances running, may perform better than having a single worker. For example 3 workers with 10 pool processes each. You need to experiment to find the numbers that works best for you, as this varies based on application, work load, task run times and other factors.

Remote control

New in version 2.0.
The **celery** command

The **celery** program is used to execute remote control commands from the command-line. It supports all of the commands listed below. See *Management Command-line Utilities (inspect/control)* for more information.

**pool support** prefork, eventlet, gevent, thread, blocking:solo (see note)

**broker support** amqp, redis

Workers have the ability to be remote controlled using a high-priority broadcast message queue. The commands can be directed to all, or a specific list of workers.

Commands can also have replies. The client can then wait for and collect those replies. Since there’s no central authority to know how many workers are available in the cluster, there’s also no way to estimate how many workers may send a reply, so the client has a configurable timeout — the deadline in seconds for replies to arrive in. This timeout defaults to one second. If the worker doesn’t reply within the deadline it doesn’t necessarily mean the worker didn’t reply, or worse is dead, but may simply be caused by network latency or the worker being slow at processing commands, so adjust the timeout accordingly.

In addition to timeouts, the client can specify the maximum number of replies to wait for. If a destination is specified, this limit is set to the number of destination hosts.

**Note:** The *solo* pool supports remote control commands, but any task executing will block any waiting control command, so it is of limited use if the worker is very busy. In that case you must increase the timeout waiting for replies in the client.

The **broadcast()** function

This is the client function used to send commands to the workers. Some remote control commands also have higher-level interfaces using **broadcast()** in the background, like **rate_limit()**, and **ping()**.

Sending the **rate_limit** command and keyword arguments:

```python
>>> app.control.broadcast('rate_limit',
... arguments={
...     'task_name': 'myapp.mytask',
...     'rate_limit': '200/m'
... })
```

This will send the command asynchronously, without waiting for a reply. To request a reply you have to use the **reply** argument:

```python
>>> app.control.broadcast('rate_limit', {
...     'task_name': 'myapp.mytask',
...     'rate_limit': '200/m'}, reply=True)
[{'worker1.example.com': 'New rate limit set successfully'},
 {'worker2.example.com': 'New rate limit set successfully'},
 {'worker3.example.com': 'New rate limit set successfully'}]
```

Using the **destination** argument you can specify a list of workers to receive the command:

```python
>>> app.control.broadcast('rate_limit', {
...     'task_name': 'myapp.mytask',
...     'rate_limit': '200/m'}, reply=True,
...     destination=['worker1@example.com'])
[{'worker1.example.com': 'New rate limit set successfully'}]
```
Of course, using the higher-level interface to set rate limits is much more convenient, but there are commands that can only be requested using `broadcast()`.

Commands

**revoke**: Revoking tasks

- **pool support**: all, terminate only supported by prefork
- **broker support**: amqp, redis

**command celery -A proj control revoke <task_id>**

All worker nodes keeps a memory of revoked task ids, either in-memory or persistent on disk (see Persistent revokes). When a worker receives a revoke request it will skip executing the task, but it won’t terminate an already executing task unless the `terminate` option is set.

**Note**: The terminate option is a last resort for administrators when a task is stuck. It’s not for terminating the task, it’s for terminating the process that’s executing the task, and that process may have already started processing another task at the point when the signal is sent, so for this reason you must never call this programmatically.

If `terminate` is set the worker child process processing the task will be terminated. The default signal sent is `TERM`, but you can specify this using the `signal` argument. Signal can be the uppercase name of any signal defined in the `signal` module in the Python Standard Library.

Terminating a task also revokes it.

**Example**

```python
>>> result.revoke()
>>>AsyncResult(id).revoke()
>>> app.control.revoke('d9078da5-9915-40a0-bfa1-392c7bde42ed')
>>> app.control.revoke('d9078da5-9915-40a0-bfa1-392c7bde42ed',
... terminate=True)
>>> app.control.revoke('d9078da5-9915-40a0-bfa1-392c7bde42ed',
... terminate=True, signal='SIGKILL')
```

**Revoking multiple tasks**

New in version 3.1.

The revoke method also accepts a list argument, where it will revoke several tasks at once.

**Example**

```python
>>> app.control.revoke([
... '7993b0aa-1f0b-4780-9af0-c47c0858b3f2',
... 'f565793e-b041-4b2b-9ca4-dca22762a55d',
... 'd9d35e03-2997-42d0-a13e-64a66b88a618',
])
```
The `GroupResult.revoke` method takes advantage of this since version 3.1.

**Persistent revokes**

Revoking tasks works by sending a broadcast message to all the workers, the workers then keep a list of revoked tasks in memory. When a worker starts up it will synchronize revoked tasks with other workers in the cluster.

The list of revoked tasks is in-memory so if all workers restart the list of revoked ids will also vanish. If you want to preserve this list between restarts you need to specify a file for these to be stored in by using the `--statedb` argument to `celery worker`:

```
$ celery -A proj worker -l info --statedb=/var/run/celery/worker.state
```

or if you use `celery multi` you want to create one file per worker instance so use the `%n` format to expand the current node name:

```
celery multi start 2 -l info --statedb=/var/run/celery/%n.state
```

See also *Variables in file paths*

Note that remote control commands must be working for revokes to work. Remote control commands are only supported by the RabbitMQ (amqp) and Redis at this point.

**Time Limits**

New in version 2.0.

`pool support` *prefork/gevent*

**Soft, or hard?**

The time limit is set in two values, *soft* and *hard*. The soft time limit allows the task to catch an exception to clean up before it is killed: the hard timeout isn’t catch-able and force terminates the task.

A single task can potentially run forever, if you have lots of tasks waiting for some event that’ll never happen you’ll block the worker from processing new tasks indefinitely. The best way to defend against this scenario happening is enabling time limits.

The time limit (*time-limit*) is the maximum number of seconds a task may run before the process executing it is terminated and replaced by a new process. You can also enable a soft time limit (*soft-time-limit*), this raises an exception the task can catch to clean up before the hard time limit kills it:

```python
from myapp import app
from celery.exceptions import SoftTimeLimitExceeded

@app.task
def mytask():
    try:
        do_work()
    except SoftTimeLimitExceeded:
        clean_up_in_a_hurry()
```

Time limits can also be set using the `task_time_limit`/`task_soft_time_limit` settings.
**Note:** Time limits don’t currently work on platforms that don’t support the SIGUSR1 signal.

### Changing time limits at run-time

New in version 2.3.

**broker support** amqp, redis

There’s a remote control command that enables you to change both soft and hard time limits for a task — named `time_limit`.

Example changing the time limit for the `tasks.crawl_the_web` task to have a soft time limit of one minute, and a hard time limit of two minutes:

```python
>>> app.control.time_limit('tasks.crawl_the_web',
                          soft=60, hard=120, reply=True)
[{'worker1.example.com': {'ok': 'time limits set successfully'}}]
```

Only tasks that starts executing after the time limit change will be affected.

### Rate Limits

### Changing rate-limits at run-time

Example changing the rate limit for the `myapp.mytask` task to execute at most 200 tasks of that type every minute:

```python
>>> app.control.rate_limit('myapp.mytask', '200/m')
```

The above doesn’t specify a destination, so the change request will affect all worker instances in the cluster. If you only want to affect a specific list of workers you can include the `destination` argument:

```python
>>> app.control.rate_limit('myapp.mytask', '200/m',
                          destination=['celery@worker1.example.com'])
```

**Warning:** This won’t affect workers with the `worker_disable_rate_limits` setting enabled.

### Max tasks per child setting

New in version 2.0.

**pool support** prefork

With this option you can configure the maximum number of tasks a worker can execute before it’s replaced by a new process.

This is useful if you have memory leaks you have no control over for example from closed source C extensions.

The option can be set using the `workers --max-tasks-per-child` argument or using the `worker_max_tasks_per_child` setting.
Max memory per child setting

New in version 4.0.

**pool support** prefork

With this option you can configure the maximum amount of resident memory a worker can execute before it’s replaced by a new process.

This is useful if you have memory leaks you have no control over for example from closed source C extensions.

The option can be set using the workers `--max-memory-per-child` argument or using the `worker_max_memory_per_child` setting.

Autoscaling

New in version 2.2.

**pool support** prefork, gevent

The autoscaler component is used to dynamically resize the pool based on load:

- The autoscaler adds more pool processes when there is work to do,
  - and starts removing processes when the workload is low.

It’s enabled by the `--autoscale` option, which needs two numbers: the maximum and minimum number of pool processes:

```
--autoscale=AUTOSCALE
  Enable autoscaling by providing max_concurrency,min_concurrency. Example:
  --autoscale=10,3 (always keep 3 processes, but grow to 10 if necessary).
```

You can also define your own rules for the autoscaler by subclassing Autoscaler. Some ideas for metrics include load average or the amount of memory available. You can specify a custom autoscaler with the `worker_autoscaler` setting.

Queues

A worker instance can consume from any number of queues. By default it will consume from all queues defined in the `task_queues` setting (that if not specified falls back to the default queue named celery).

You can specify what queues to consume from at start-up, by giving a comma separated list of queues to the `-Q` option:

```
$ celery -A proj worker -l info -Q foo,bar,baz
```

If the queue name is defined in `task_queues` it will use that configuration, but if it’s not defined in the list of queues Celery will automatically generate a new queue for you (depending on the `task_create_missing_queues` option).

You can also tell the worker to start and stop consuming from a queue at run-time using the remote control commands `add_consumer` and `cancel_consumer`. 
Queues: Adding consumers

The `add_consumer` control command will tell one or more workers to start consuming from a queue. This operation is idempotent.

To tell all workers in the cluster to start consuming from a queue named “foo” you can use the `celery control` program:

```
$ celery -A proj control add_consumer foo
-> worker1.local: OK
    started consuming from u'foo'
```

If you want to specify a specific worker you can use the `--destination` argument:

```
$ celery -A proj control add_consumer foo -d celery@worker1.local
```

The same can be accomplished dynamically using the `app.control.add_consumer()` method:

```
>>> app.control.add_consumer('foo', reply=True)
[(u'worker1.local': {u'ok': u'already consuming from u'foo'})]
```

By now we’ve only shown examples using automatic queues, If you need more control you can also specify the exchange, routing_key and even other options:

```
>>> app.control.add_consumer('foo', exchange='ex', routing_key='media.*', reply=True, destination=['w1@example.com', 'w2@example.com'])
```

Queues: Canceling consumers

You can cancel a consumer by queue name using the `cancel_consumer` control command.

To force all workers in the cluster to cancel consuming from a queue you can use the `celery control` program:

```
$ celery -A proj control cancel_consumer foo
```

The `--destination` argument can be used to specify a worker, or a list of workers, to act on the command:

```
$ celery -A proj control cancel_consumer foo -d celery@worker1.local
```

You can also cancel consumers programmatically using the `app.control.cancel_consumer()` method:

```
>>> app.control.cancel_consumer('foo', reply=True)
[(u'worker1.local': {u'ok': u'no longer consuming from u'foo'}])
```
Queues: List of active queues

You can get a list of queues that a worker consumes from by using the `active_queues` control command:

```
$ celery -A proj inspect active_queues
[...]
```

Like all other remote control commands this also supports the `--destination` argument used to specify the workers that should reply to the request:

```
$ celery -A proj inspect active_queues -d celery@worker1.local
[...]
```

This can also be done programmatically by using the `app.control.inspect.active_queues()` method:

```python
>>> app.control.inspect().active_queues()
[...]
```

Inspecting workers

`app.control.inspect` lets you inspect running workers. It uses remote control commands under the hood.

You can also use the `celery` command to inspect workers, and it supports the same commands as the `app.control` interface.

```python
>>> # Inspect all nodes.
>>> i = app.control.inspect()

>>> # Specify multiple nodes to inspect.
>>> i = app.control.inspect(['worker1.example.com', 'worker2.example.com'])

>>> # Specify a single node to inspect.
>>> i = app.control.inspect('worker1.example.com')
```

Dump of registered tasks

You can get a list of tasks registered in the worker using the `registered()`:

```python
>>> i.registered()
[{'worker1.example.com': ['tasks.add', 'tasks.sleeptask']}]```

Dump of currently executing tasks

You can get a list of active tasks using `active()`:
Dump of scheduled (ETA) tasks

You can get a list of tasks waiting to be scheduled by using `scheduled()`:

```python
>>> i.scheduled()
[{'worker1.example.com': [{'eta': '2010-06-07 09:07:52', 'priority': 0,
'request': {
'name': 'tasks.sleeptask',
'id': '1a7980ea-8b19-413e-91d2-0b74f3844c4d',
'args': '[1]',
'kwargs': '{}'}},
{'eta': '2010-06-07 09:07:53', 'priority': 0,
'request': {
'name': 'tasks.sleeptask',
'id': '49661b9a-aa22-4120-94b7-9ee8031d219d',
'args': '[2]',
'kwargs': '{}'}]}]
```

Note: These are tasks with an ETA/countdown argument, not periodic tasks.

Dump of reserved tasks

Reserved tasks are tasks that have been received, but are still waiting to be executed.

You can get a list of these using `reserved()`:

```python
>>> i.reserved()
[{'worker1.example.com': [{'name': 'tasks.sleeptask',
'id': '32666e9b-809c-41fa-8e93-5ae0c80afbbf',
'args': '(8,)',
'kwargs': '{}'}]]
```

Statistics

The remote control command `inspect stats` (or `stats()`) will give you a long list of useful (or not so useful) statistics about the worker:

```
$ celery -A proj inspect stats
```

The output will include the following fields:

- broker
Section for broker information.

- **connect_timeout**
  
  Timeout in seconds (int/float) for establishing a new connection.

- **heartbeat**
  
  Current heartbeat value (set by client).

- **hostname**
  
  Node name of the remote broker.

- **insist**
  
  No longer used.

- **login_method**
  
  Login method used to connect to the broker.

- **port**
  
  Port of the remote broker.

- **ssl**
  
  SSL enabled/disabled.

- **transport**
  
  Name of transport used (e.g., amqp or redis)

- **transport_options**
  
  Options passed to transport.

- **uri_prefix**
  
  Some transports expects the host name to be a URL.

  
  ```
  redis+socket:///tmp/redis.sock
  ```

  In this example the URI-prefix will be redis.

- **userid**
  
  User id used to connect to the broker with.

- **virtual_host**
  
  Virtual host used.

- **clock**
  
  Value of the workers logical clock. This is a positive integer and should be increasing every time you receive statistics.

- **pid**
  
  Process id of the worker instance (Main process).

- **pool**
  
  Pool-specific section.

  - **max-concurrency**
    
    Max number of processes/threads/green threads.
- `max-tasks-per-child`
  Max number of tasks a thread may execute before being recycled.

- `processes`
  List of PIDs (or thread-id’s).

- `put-guarded-by-semaphore`
  Internal

- `timeouts`
  Default values for time limits.

- `writes`
  Specific to the prefork pool, this shows the distribution of writes to each process in the pool when using async I/O.

- `prefetch_count`
  Current prefetch count value for the task consumer.

- `rusage`
  System usage statistics. The fields available may be different on your platform.
  From `getrusage(2)`:
    - `stime`
      Time spent in operating system code on behalf of this process.
    - `utime`
      Time spent executing user instructions.
    - `maxrss`
      The maximum resident size used by this process (in kilobytes).
    - `idrss`
      Amount of non-shared memory used for data (in kilobytes times ticks of execution)
    - `isrss`
      Amount of non-shared memory used for stack space (in kilobytes times ticks of execution)
    - `ixrss`
      Amount of memory shared with other processes (in kilobytes times ticks of execution).
    - `inblock`
      Number of times the file system had to read from the disk on behalf of this process.
    - `oublock`
      Number of times the file system has to write to disk on behalf of this process.
    - `majflt`
      Number of page faults that were serviced by doing I/O.
    - `minflt`
      Number of page faults that were serviced without doing I/O.
- **msgrcv**: Number of IPC messages received.
- **msgsnd**: Number of IPC messages sent.
- **nvcsw**: Number of times this process voluntarily invoked a context switch.
- **nivcsw**: Number of times an involuntary context switch took place.
- **nsignals**: Number of signals received.
- **nswap**: The number of times this process was swapped entirely out of memory.

• **total**: Map of task names and the total number of tasks with that type the worker has accepted since start-up.

### Additional Commands

#### Remote shutdown

This command will gracefully shut down the worker remotely:

```python
>>> app.control.broadcast('shutdown') # shutdown all workers
>>> app.control.broadcast('shutdown', destination='worker1@example.com')
```

#### Ping

This command requests a ping from alive workers. The workers reply with the string ‘pong’, and that’s just about it. It will use the default one second timeout for replies unless you specify a custom timeout:

```python
>>> app.control.ping(timeout=0.5)
[{'worker1.example.com': 'pong'},
 {'worker2.example.com': 'pong'},
 {'worker3.example.com': 'pong'}]
```

`ping()` also supports the `destination` argument, so you can specify the workers to ping:

```python
>>> ping(['worker2.example.com', 'worker3.example.com'])
[{'worker2.example.com': 'pong'},
 {'worker3.example.com': 'pong'}]
```

#### Enable/disable events

You can enable/disable events by using the `enable_events`, `disable_events` commands. This is useful to temporarily monitor a worker using `celery_events/celerymon`. 
Writing your own remote control commands

There are two types of remote control commands:

- **Inspect command**
  
  Does not have side effects, will usually just return some value found in the worker, like the list of currently registered tasks, the list of active tasks, etc.

- **Control command**
  
  Performs side effects, like adding a new queue to consume from.

Remote control commands are registered in the control panel and they take a single argument: the current `ControlDispatch` instance. From there you have access to the active `Consumer` if needed.

Here’s an example control command that increments the task prefetch count:

```python
from celery.worker.control import control_command

@control_command(
    args=[('n', int)],
    signature='[N=1]',  # <- used for help on the command-line.
)
def increase_prefetch_count(state, n=1):
    state.consumer.qos.increment_eventually(n)
    return {'ok': 'prefetch count incremented'}
```

Make sure you add this code to a module that is imported by the worker: this could be the same module as where your Celery app is defined, or you can add the module to the `imports` setting.

Restart the worker so that the control command is registered, and now you can call your command using the `celery control` utility:

```
$ celery -A proj control increase_prefetch_count 3
```

You can also add actions to the `celery inspect` program, for example one that reads the current prefetch count:

```python
from celery.worker.control import inspect_command

@inspect_command
def current_prefetch_count(state):
    return {'prefetch_count': state.consumer.qos.value}
```

After restarting the worker you can now query this value using the `celery inspect` program:

```
$ celery -A proj inspect current_prefetch_count
```

### 3.6 Daemonization

- **Generic init-scripts**
Most Linux distributions these days use systemd for managing the lifecycle of system and user services.

You can check if your Linux distribution uses systemd by typing:

```
$ systemd --version
```

```
systemd 237
+PAM +AUDIT +SELINUX +IMA +APPARMOR +SMACK +SYSVINIT +UTMP +LIBCRYPTSETUP +GCRYPT+
  →+GNUTLS +ACL +XZ +LZ4 +SECCOMP +BLKID +ELFUTILS +KMOD -IDN2 +IDN -PCRE2 default-
  →hierarchy=hybrid
```

If you have output similar to the above, please refer to our systemd documentation for guidance.

However, the init.d script should still work in those Linux distributions as well since systemd provides the systemd-sysv compatibility layer which generates services automatically from the init.d scripts we provide.

If you package Celery for multiple Linux distributions and some do not support systemd or to other Unix systems as well, you may want to refer to our init.d documentation.

**Generic init-scripts**

See the `extra/generic-init.d/` directory Celery distribution.

This directory contains generic bash init-scripts for the **celery worker** program, these should run on Linux, FreeBSD, OpenBSD, and other Unix-like platforms.

**Init-script: celeryd**

```
Usage `/etc/init.d/celeryd {start|stop|restart|status}
```
Configuration file /etc/default/celeryd

To configure this script to run the worker properly you probably need to at least tell it where to change directory to when it starts (to find the module containing your app, or your configuration module).

The daemonization script is configured by the file /etc/default/celeryd. This is a shell (sh) script where you can add environment variables like the configuration options below. To add real environment variables affecting the worker you must also export them (e.g., `export DISPLAY=:0`)

Superuser privileges required

The init-scripts can only be used by root, and the shell configuration file must also be owned by root.

Unprivileged users don’t need to use the init-script, instead they can use the celery multi utility (or celery worker --detach):

```
$ celery multi start worker1 \
  -A proj \
  --pidfile="$HOME/run/celery/%n.pid" \
  --logfile="$HOME/log/celery/%n%I.log"

$ celery multi restart worker1 \
  -A proj \
  --logfile="$HOME/log/celery/%n%I.log" \
  --pidfile="$HOME/run/celery/%n.pid"

$ celery multi stopwait worker1 --pidfile="$HOME/run/celery/%n.pid"
```

Example configuration

This is an example configuration for a Python project.

/etc/default/celeryd:

```
# Names of nodes to start
# most people will only start one node:
CELERYD_NODES="worker1"
# but you can also start multiple and configure settings
# for each in CELERYD_OPTS
#CELERYD_NODES="worker1 worker2 worker3"
# alternatively, you can specify the number of nodes to start:
#CELERYD_NODES=10

# Absolute or relative path to the 'celery' command:
CELERY_BIN="/usr/local/bin/celery"
#CELERY_BIN="/virtualenvs/def/bin/celery"

# App instance to use
# comment out this line if you don't use an app
CELERY_APP="proj"
# or fully qualified:
#CELERY_APP="proj.tasks:app"

# Where to chdir at start.
CELERYD_CHDIR="/opt/Myproject/"
```

(continues on next page)
# Extra command-line arguments to the worker

CELERYD_OPTS="--time-limit=300 --concurrency=8"

# Configure node-specific settings by appending node name to arguments:

#CELERYD_OPTS="--time-limit=300 -c 8 -c:worker2 4 -c:worker3 2 -Ofair:worker1"

# Set logging level to DEBUG
CELERYD_LOG_LEVEL="DEBUG"

# %n will be replaced with the first part of the nodename.
CELERYD_LOG_FILE="/var/log/celery/%n%I.log"
CELERYD_PID_FILE="/var/run/celery/%n.pid"

# Workers should run as an unprivileged user.
# You need to create this user manually (or you can choose
# a user/group combination that already exists (e.g., nobody).
CELERYD_USER="celery"
CELERYD_GROUP="celery"

# If enabled pid and log directories will be created if missing,
# and owned by the userid/group configured.
CELERY_CREATE_DIRS=1

Using a login shell

You can inherit the environment of the CELERYD_USER by using a login shell:

CELERYD_SU_ARGS="-l"

Note that this isn’t recommended, and that you should only use this option when absolutely necessary.

Example Django configuration

Django users now uses the exact same template as above, but make sure that the module that defines your Celery app instance also sets a default value for DJANGO_SETTINGS_MODULE as shown in the example Django project in First steps with Django.

Available options

- **CELERY_APP**

  App instance to use (value for --app argument).

- **CELERY_BIN**

  Absolute or relative path to the celery program. Examples:

  - celery
  - /usr/local/bin/celery
  - /virtualenvs/proj/bin/celery
  - /virtualenvs/proj/bin/python -m celery

- **CELERYD_NODES**
List of node names to start (separated by space).

- **CELERYD_OPTS**
  Additional command-line arguments for the worker, see `celery worker --help` for a list. This also supports the extended syntax used by `multi` to configure settings for individual nodes. See `celery multi --help` for some multi-node configuration examples.

- **CELERYD_CHDIR**
  Path to change directory to at start. Default is to stay in the current directory.

- **CELERYD_PID_FILE**
  Full path to the PID file. Default is `/var/run/celery/%n.pid`

- **CELERYD_LOG_FILE**
  Full path to the worker log file. Default is `/var/log/celery/%n%I.log` **Note**: Using `%I` is important when using the prefork pool as having multiple processes share the same log file will lead to race conditions.

- **CELERYD_LOG_LEVEL**
  Worker log level. Default is INFO.

- **CELERYD_USER**
  User to run the worker as. Default is current user.

- **CELERYD_GROUP**
  Group to run worker as. Default is current user.

- **CELERY_CREATE_DIRS**
  Always create directories (log directory and pid file directory). Default is to only create directories when no custom logfile/pidfile set.

- **CELERY_CREATE_RUNDIR**
  Always create pidfile directory. By default only enabled when no custom pidfile location set.

- **CELERY_CREATE_LOGDIR**
  Always create logfile directory. By default only enable when no custom logfile location set.

**Init-script:** celerybeat

**Usage**  
`/etc/init.d/celerybeat {start|stop|restart}`

**Configuration file**  
`/etc/default/celerybeat` or `/etc/default/celeryd`.

**Example configuration**

This is an example configuration for a Python project:

```
/etc/default/celerybeat:

# Absolute or relative path to the 'celery' command:
CELERY_BIN="/usr/local/bin/celery"
#CELERY_BIN="/virtualenvs/def/bin/celery"
```

(continues on next page)
# App instance to use
# comment out this line if you don't use an app
CELERY_APP="proj"
# or fully qualified:
#CELERY_APP="proj.tasks:app"

# Where to chdir at start.
CELERYBEAT_CHDIR="/opt/Myproject/"

# Extra arguments to celerybeat
CELERYBEAT_OPTS="--schedule=/var/run/celery/celerybeat-schedule"

Example Django configuration

You should use the same template as above, but make sure the DJANGO_SETTINGS_MODULE variable is set (and exported), and that CELERYD_CHDIR is set to the projects directory:

```bash
export DJANGO_SETTINGS_MODULE="settings"
CELERYD_CHDIR="/opt/MyProject"
```

Available options

- **CELERY_APP**
  - App instance to use (value for --app argument).

- **CELERYBEAT_OPTS**
  - Additional arguments to celery beat, see celery beat --help for a list of available options.

- **CELERYBEAT_PID_FILE**
  - Full path to the PID file. Default is /var/run/celeryd.pid.

- **CELERYBEAT_LOG_FILE**
  - Full path to the log file. Default is /var/log/celeryd.log.

- **CELERYBEAT_LOG_LEVEL**
  - Log level to use. Default is INFO.

- **CELERYBEAT_USER**
  - User to run beat as. Default is the current user.

- **CELERYBEAT_GROUP**
  - Group to run beat as. Default is the current user.

- **CELERY_CREATE_DIRS**
  - Always create directories (log directory and pid file directory). Default is to only create directories when no custom logfile/pidfile set.

- **CELERY_CREATE_RUNDIR**
  - Always create pidfile directory. By default only enabled when no custom pidfile location set.
• **CELERY_CREATE_LogDIR**
  
  Always create logfile directory. By default only enable when no custom logfile location set.

**Troubleshooting**

If you can’t get the init-scripts to work, you should try running them in *verbose mode*:

```bash
# sh -x /etc/init.d/celeryd start
```

This can reveal hints as to why the service won’t start.

If the worker starts with “OK” but exits almost immediately afterwards and there’s no evidence in the log file, then there’s probably an error but as the daemons standard outputs are already closed you’ll not be able to see them anywhere. For this situation you can use the `C_FAKEFORK` environment variable to skip the daemonization step:

```bash
# C_FAKEFORK=1 sh -x /etc/init.d/celeryd start
```

and now you should be able to see the errors.

Commonly such errors are caused by insufficient permissions to read from, or write to a file, and also by syntax errors in configuration modules, user modules, third-party libraries, or even from Celery itself (if you’ve found a bug you should *report it*).

**Usage systemd**

- `extra/systemd/`

  **Usage** `systemctl {start|stop|restart|status} celery.service`

  **Configuration file** `/etc/conf.d/celery`

**Service file: celery.service**

This is an example systemd file:

```
/etc/systemd/system/celery.service:

[Unit]
Description=Celery Service
After=network.target

[Service]
Type=forking
User=celery
Group=celery
EnvironmentFile=/etc/conf.d/celery
WorkingDirectory=/opt/celery
ExecStart=/bin/sh -c '(${CELERY_BIN} multi start ${CELERYD_NODES} \
   -A ${CELERY_APP} --pidfile=${CELERYD_PID_FILE} \n   --logfile=${CELERYD_LOG_FILE} --loglevel=${CELERYD_LOG_LEVEL} ${CELERYD_OPTS})'
ExecStop=/bin/sh -c '(${CELERY_BIN} multi stopwait ${CELERYD_NODES} \
   --pidfile=${CELERYD_PID_FILE})'
ExecReload=/bin/sh -c '(${CELERY_BIN} multi restart ${CELERYD_NODES} \
   -A ${CELERY_APP} --pidfile=${CELERYD_PID_FILE} \n   --logfile=${CELERYD_LOG_FILE} --loglevel=${CELERYD_LOG_LEVEL} ${CELERYD_OPTS})'
```

(continues on next page)
[Install]
WantedBy=multi-user.target

Once you’ve put that file in `/etc/systemd/system`, you should run `systemctl daemon-reload` in order that Systemd acknowledges that file. You should also run that command each time you modify it.

To configure user, group, chdir change settings: User, Group, and WorkingDirectory defined in `/etc/systemd/system/celery.service`.

You can also use systemd-tmpfiles in order to create working directories (for logs and pid).

```
file /etc/tmpfiles.d/celery.conf

d /var/run/celery 0755 celery celery -
d /var/log/celery 0755 celery celery -
```

Example configuration

This is an example configuration for a Python project:

```
/etc/conf.d/celery:

# Name of nodes to start
# here we have a single node
CELEYD_NODES="w1"
# or we could have three nodes:
#CELEYD_NODES="w1 w2 w3"

# Absolute or relative path to the 'celery' command:
CELEY_BIN="/usr/local/bin/celery"
#CELEY_BIN="/virtualenvs/def/bin/celery"

# App instance to use
# comment out this line if you don't use an app
CELEY_APP="proj"
# or fully qualified:
#CELEY_APP="proj.tasks:app"

# How to call manage.py
CELEYD_MULTI="multi"

# Extra command-line arguments to the worker
CELEYD_OPTS="--time-limit=300 --concurrency=8"

# - %n will be replaced with the first part of the nodename.
# - %I will be replaced with the current child process index
# and is important when using the prefork pool to avoid race conditions.
CELEYD_PID_FILE="/var/run/celery/%n.pid"
CELEYD_LOG_FILE="/var/log/celery/%n%I.log"
CELEYD_LOG_LEVEL="INFO"

# you may wish to add these options for Celery Beat
CELEYBEAT_PID_FILE="/var/run/celery/beat.pid"
CELEYBEAT_LOG_FILE="/var/log/celery/beat.log"
```
Service file: celerybeat.service

This is an example systemd file for Celery Beat:

```
[Unit]
Description=Celery Beat Service
After=network.target

[Service]
Type=simple
User=celery
Group=celery
EnvironmentFile=/etc/conf.d/celery
WorkingDirectory=/opt/celery
ExecStart=/bin/sh -c '{CELERY_BIN} beat
   -A {CELERY_APP} --pidfile={CELERYBEAT_PID_FILE}
   --logfile={CELERYBEAT_LOG_FILE} --loglevel={CELERYD_LOG_LEVEL}'

[Install]
WantedBy=multi-user.target
```

Running the worker with superuser privileges (root)

Running the worker with superuser privileges is a very dangerous practice. There should always be a workaround to avoid running as root. Celery may run arbitrary code in messages serialized with pickle - this is dangerous, especially when run as root.

By default Celery won’t run workers as root. The associated error message may not be visible in the logs but may be seen if C_FAKEFORK is used.

To force Celery to run workers as root use C_FORCE_ROOT.

When running as root without C_FORCE_ROOT the worker will appear to start with “OK” but exit immediately after with no apparent errors. This problem may appear when running the project in a new development or production environment (inadvertently) as root.

launchd (macOS)

- extra/macOS

3.3.7 Periodic Tasks

- Introduction
- Time Zones
Introduction

celery beat is a scheduler: It kicks off tasks at regular intervals, that are then executed by available worker nodes in the cluster.

By default the entries are taken from the beat_schedule setting, but custom stores can also be used, like storing the entries in a SQL database.

You have to ensure only a single scheduler is running for a schedule at a time, otherwise you’d end up with duplicate tasks. Using a centralized approach means the schedule doesn’t have to be synchronized, and the service can operate without using locks.

Time Zones

The periodic task schedules uses the UTC time zone by default, but you can change the time zone used using the timezone setting.

An example time zone could be Europe/London:

```python
timezone = 'Europe/London'
```

This setting must be added to your app, either by configuring it directly using (app.conf.timezone = 'Europe/London'), or by adding it to your configuration module if you have set one up using app. config_from_object. See Configuration for more information about configuration options.

The default scheduler (storing the schedule in the celerybeat-schedule file) will automatically detect that the time zone has changed, and so will reset the schedule itself, but other schedulers may not be so smart (e.g., the Django database scheduler, see below) and in that case you’ll have to reset the schedule manually.

Django Users

Celery recommends and is compatible with the new USE_TZ setting introduced in Django 1.4.

For Django users the time zone specified in the TIME_ZONE setting will be used, or you can specify a custom time zone for Celery alone by using the timezone setting.

The database scheduler won’t reset when timezone related settings change, so you must do this manually:

```bash
$ python manage.py shell
>>> from djcelery.models import PeriodicTask
>>> PeriodicTask.objects.update(last_run_at=None)
```

Django-Celery only supports Celery 4.0 and below, for Celery 4.0 and above, do as follow:

```python
timezone = 'Europe/London'
```
Entries

To call a task periodically you have to add an entry to the beat schedule list.

```python
from celery import Celery
from celery.schedules import crontab

app = Celery()

@app.on_after_configure.connect
def setup_periodic_tasks(sender, **kwargs):
    # Calls test('hello') every 10 seconds.
    sender.add_periodic_task(10.0, test.s('hello'), name='add every 10')

    # Calls test('world') every 30 seconds
    sender.add_periodic_task(30.0, test.s('world'), expires=10)

    # Executes every Monday morning at 7:30 a.m.
    sender.add_periodic_task(
        crontab(hour=7, minute=30, day_of_week=1),
        test.s('Happy Mondays!'),
    )

@app.task
def test(arg):
    print(arg)
```

Setting these up from within the `on_after_configure` handler means that we’ll not evaluate the app at module level when using `test.s()`.

The `add_periodic_task()` function will add the entry to the `beat_schedule` setting behind the scenes, and the same setting can also be used to set up periodic tasks manually:

Example: Run the `tasks.add` task every 30 seconds.

```python
app.conf.beat_schedule = {
    'add-every-30-seconds': {
        'task': 'tasks.add',
        'schedule': 30.0,
        'args': (16, 16)
    },
}
app.conf.timezone = 'UTC'
```

Note: If you’re wondering where these settings should go then please see `Configuration`. You can either set these options on your app directly or you can keep a separate module for configuration.

If you want to use a single item tuple for `args`, don’t forget that the constructor is a comma, and not a pair of parentheses.
Using a `timedelta` for the schedule means the task will be sent in 30 second intervals (the first task will be sent 30 seconds after `celery beat` starts, and then every 30 seconds after the last run).

A Crontab like schedule also exists, see the section on `Crontab schedules`.

Like with `cron`, the tasks may overlap if the first task doesn’t complete before the next. If that’s a concern you should use a locking strategy to ensure only one instance can run at a time (see for example `Ensuring a task is only executed one at a time`).

### Available Fields

- **task**
  
  The name of the task to execute.

- **schedule**
  
  The frequency of execution.
  
  This can be the number of seconds as an integer, a `timedelta`, or a `crontab`. You can also define your own custom schedule types, by extending the interface of `schedule`.

- **args**
  
  Positional arguments (`list` or `tuple`).

- **kwargs**
  
  Keyword arguments (`dict`).

- **options**
  
  Execution options (`dict`).
  
  This can be any argument supported by `apply_async()` – `exchange`, `routing_key`, `expires`, and so on.

- **relative**
  
  If `relative` is true `timedelta` schedules are scheduled “by the clock.” This means the frequency is rounded to the nearest second, minute, hour or day depending on the period of the `timedelta`.

  By default `relative` is false, the frequency isn’t rounded and will be relative to the time when `celery beat` was started.

### Crontab schedules

If you want more control over when the task is executed, for example, a particular time of day or day of the week, you can use the `crontab` schedule type:

```python
from celery.schedules import crontab

app.conf.beat_schedule = {
    # Executes every Monday morning at 7:30 a.m.
    'add-every-monday-morning': {
        'task': 'tasks.add',
        'schedule': crontab(hour=7, minute=30, day_of_week=1),
        'args': (16, 16),
    },
}
```
The syntax of these Crontab expressions are very flexible. Some examples:

<table>
<thead>
<tr>
<th>Example</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>crontab()</code></td>
<td>Execute every minute.</td>
</tr>
<tr>
<td><code>crontab(minute=0, hour=0)</code></td>
<td>Execute daily at midnight.</td>
</tr>
<tr>
<td><code>crontab(minute=0, hour='*/3')</code></td>
<td>Execute every three hours: midnight, 3am, 6am, 9am, noon, 3pm, 6pm, 9pm.</td>
</tr>
<tr>
<td><code>crontab(minute=0, hour='0,3,6,9,12,15,18,21')</code></td>
<td>Same as previous.</td>
</tr>
<tr>
<td><code>crontab(minute='*/15')</code></td>
<td>Execute every 15 minutes.</td>
</tr>
<tr>
<td><code>crontab(day_of_week='sunday')</code></td>
<td>Execute every minute (!) at Sundays.</td>
</tr>
<tr>
<td><code>crontab(minute='*', hour='*', day_of_week='sun')</code></td>
<td>Same as previous.</td>
</tr>
<tr>
<td><code>crontab(minute='*/10', hour='3,17,22', day_of_week='thu,fri')</code></td>
<td>Execute every ten minutes, but only between 3-4 am, 5-6 pm, and 10-11 pm on Thursdays or Fridays.</td>
</tr>
<tr>
<td><code>crontab(minute='*/2,*/3')</code></td>
<td>Execute every hour, and every hour divisible by three. This means: at every hour except: 1am, 5am, 7am, 11am, 1pm, 5pm, 7pm, 11pm</td>
</tr>
<tr>
<td><code>crontab(minute='*/5')</code></td>
<td>Execute hour divisible by 5. This means that it is triggered at 3pm, not 5pm (since 3pm equals the 24-hour clock value of “15”, which is divisible by 5).</td>
</tr>
<tr>
<td><code>crontab(minute='*/3,8-17')</code></td>
<td>Execute every hour divisible by 3, and every hour during office hours (8am-5pm).</td>
</tr>
<tr>
<td><code>crontab(0, 0, day_of_month='2')</code></td>
<td>Execute on the second day of every month.</td>
</tr>
<tr>
<td><code>crontab(0, 0, day_of_month='2-30/2')</code></td>
<td>Execute on every even numbered day.</td>
</tr>
<tr>
<td><code>crontab(0, 0, day_of_month='1-7,15-21')</code></td>
<td>Execute on the first and third weeks of the month.</td>
</tr>
<tr>
<td><code>crontab(0, 0, day_of_month='11', month_of_year='5')</code></td>
<td>Execute on the eleventh of May every year.</td>
</tr>
<tr>
<td><code>crontab(0, 0, month_of_year='*/3')</code></td>
<td>Execute every day on the first month of every quarter.</td>
</tr>
</tbody>
</table>

See `celery.schedules.crontab` for more documentation.

**Solar schedules**

If you have a task that should be executed according to sunrise, sunset, dawn or dusk, you can use the `solar` schedule type:

```
from celery.schedules import solar
```

(continues on next page)
app.conf.beat_schedule = {
    # Executes at sunset in Melbourne
    'add-at-melbourne-sunset': {
        'task': 'tasks.add',
        'schedule': solar('sunset', -37.81753, 144.96715),
        'args': (16, 16),
    },
}

The arguments are simply: `solar(event, latitude, longitude)`

Be sure to use the correct sign for latitude and longitude:

<table>
<thead>
<tr>
<th>Sign</th>
<th>Argument</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>+</td>
<td>latitude</td>
<td>North</td>
</tr>
<tr>
<td>-</td>
<td>latitude</td>
<td>South</td>
</tr>
<tr>
<td>+</td>
<td>longitude</td>
<td>East</td>
</tr>
<tr>
<td>-</td>
<td>longitude</td>
<td>West</td>
</tr>
</tbody>
</table>

Possible event types are:

<table>
<thead>
<tr>
<th>Event</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>dawn_astronomical</td>
<td>Execute at the moment after which the sky is no longer completely dark. This is when the sun is 18 degrees below the horizon.</td>
</tr>
<tr>
<td>dawn_nautical</td>
<td>Execute when there’s enough sunlight for the horizon and some objects to be distinguishable; formally, when the sun is 12 degrees below the horizon.</td>
</tr>
<tr>
<td>dawn_civil</td>
<td>Execute when there’s enough light for objects to be distinguishable so that outdoor activities can commence; formally, when the Sun is 6 degrees below the horizon.</td>
</tr>
<tr>
<td>sunrise</td>
<td>Execute when the upper edge of the sun appears over the eastern horizon in the morning.</td>
</tr>
<tr>
<td>solar_noon</td>
<td>Execute when the sun is highest above the horizon on that day.</td>
</tr>
<tr>
<td>sunset</td>
<td>Execute when the trailing edge of the sun disappears over the western horizon in the evening.</td>
</tr>
<tr>
<td>dusk_civil</td>
<td>Execute at the end of civil twilight, when objects are still distinguishable and some stars and planets are visible. Formally, when the sun is 6 degrees below the horizon.</td>
</tr>
<tr>
<td>dusk_nautical</td>
<td>Execute when the sun is 12 degrees below the horizon. Objects are no longer distinguishable, and the horizon is no longer visible to the naked eye.</td>
</tr>
<tr>
<td>dusk_astronomical</td>
<td>Execute at the moment after which the sky becomes completely dark; formally, when the sun is 18 degrees below the horizon.</td>
</tr>
</tbody>
</table>

All solar events are calculated using UTC, and are therefore unaffected by your timezone setting.

In polar regions, the sun may not rise or set every day. The scheduler is able to handle these cases (i.e., a `sunrise` event won’t run on a day when the sun doesn’t rise). The one exception is `solar_noon`, which is formally defined as the moment the sun transits the celestial meridian, and will occur every day even if the sun is below the horizon.

Twilight is defined as the period between dawn and sunrise; and between sunset and dusk. You can schedule an event according to "twilight" depending on your definition of twilight (civil, nautical, or astronomical), and whether you want the event to take place at the beginning or end of twilight, using the appropriate event from the list above.

See `celery.schedules.solar` for more documentation.

**Starting the Scheduler**

To start the `celery beat` service:
You can also embed `beat` inside the worker by enabling the workers `--B` option, this is convenient if you’ll never run more than one worker node, but it’s not commonly used and for that reason isn’t recommended for production use:

```
$ celery -A proj worker --B
```

Beat needs to store the last run times of the tasks in a local database file (named `celerybeat-schedule` by default), so it needs access to write in the current directory, or alternatively you can specify a custom location for this file:

```
$ celery -A proj beat -s /home/celery/var/run/celerybeat-schedule
```

**Note:** To daemonize beat see *Daemonization.*

### Using custom scheduler classes

Custom scheduler classes can be specified on the command-line (the `--scheduler` argument).

The default scheduler is the `celery.beat.PersistentScheduler`, that simply keeps track of the last run times in a local `shelve` database file.

There’s also the `django-celery-beat` extension that stores the schedule in the Django database, and presents a convenient admin interface to manage periodic tasks at runtime.

To install and use this extension:

1. Use `pip` to install the package:

   ```
   $ pip install django-celery-beat
   ```

2. Add the `django_celery_beat` module to `INSTALLED_APPS` in your Django project’s `settings.py`:

   ```
   INSTALLED_APPS = (
       ...
       'django_celery_beat',
   )
   ```

   Note that there is no dash in the module name, only underscores.

3. Apply Django database migrations so that the necessary tables are created:

   ```
   $ python manage.py migrate
   ```

4. Start the `celery beat` service using the `django_celery_beat` scheduler:

   ```
   $ celery -A proj beat -l info --scheduler django_celery_beat.schedulers:DatabaseScheduler
   ```

   Note: You may also add this as the `beat_scheduler` setting directly.

5. Visit the Django-Admin interface to set up some periodic tasks.
3.3.8 Routing Tasks

**Note:** Alternate routing concepts like topic and fanout is not available for all transports, please consult the transport comparison table.

- **Basics**
  - Automatic routing
    - Changing the name of the default queue
    - How the queues are defined
  - Manual routing

**Basics**

**Automatic routing**

The simplest way to do routing is to use the `task_create_missing_queues` setting (on by default).

With this setting on, a named queue that’s not already defined in `task_queues` will be created automatically. This makes it easy to perform simple routing tasks.

Say you have two servers, x, and y that handle regular tasks, and one server z, that only handles feed related tasks. You can use this configuration:
With this route enabled import feed tasks will be routed to the “feeds” queue, while all other tasks will be routed to the default queue (named “celery” for historical reasons).

Alternatively, you can use glob pattern matching, or even regular expressions, to match all tasks in the feed.tasks name-space:

```python
app.conf.task_routes = {'feed.tasks.import_feed': {'queue': 'feeds'}}
```

If the order of matching patterns is important you should specify the router in items format instead:

```python
app.conf.task_routes = [{'feed.tasks.*': {'queue': 'feeds'}},
                       {'web.tasks.*': {'queue': 'web'}},
                       {'re.compile(r'(video|image)\..*'): {'queue': 'media'}}]
```

Note: The task_routes setting can either be a dictionary, or a list of router objects, so in this case we need to specify the setting as a tuple containing a list.

After installing the router, you can start server z to only process the feeds queue like this:

```
user@z:/$ celery -A proj worker -Q feeds
```

You can specify as many queues as you want, so you can make this server process the default queue as well:

```
user@z:/$ celery -A proj worker -Q feeds,celery
```

### Changing the name of the default queue

You can change the name of the default queue by using the following configuration:

```python
app.conf.task_default_queue = 'default'
```

### How the queues are defined

The point with this feature is to hide the complex AMQP protocol for users with only basic needs. However – you may still be interested in how these queues are declared.

A queue named “video” will be created with the following settings:

```python
{'exchange': 'video',
 'exchange_type': 'direct',
 'routing_key': 'video'}
```

The non-AMQP backends like Redis or SQS don’t support exchanges, so they require the exchange to have the same name as the queue. Using this design ensures it will work for them as well.
**Manual routing**

Say you have two servers, $x$, and $y$ that handle regular tasks, and one server $z$, that only handles feed related tasks, you can use this configuration:

```
from kombu import Queue

app.conf.task_default_queue = 'default'
app.conf.task_queues = {
    Queue('default', routing_key='task.#'),
    Queue('feed_tasks', routing_key='feed.#'),
}
app.conf.task_default_exchange = 'tasks'
app.conf.task_default_exchange_type = 'topic'
app.conf.task_default_routing_key = 'task.default'
```

`task_queues` is a list of `Queue` instances. If you don’t set the exchange or exchange type values for a key, these will be taken from the `task_default_exchange` and `task_default_exchange_type` settings.

To route a task to the `feed_tasks` queue, you can add an entry in the `task_routes` setting:

```
task_routes = {
    'feeds.tasks.import_feed': {
        'queue': 'feed_tasks',
        'routing_key': 'feed.import',
    },
}
```

You can also override this using the `routing_key` argument to `Task.apply_async()`, or `send_task()`:

```
>>> from feeds.tasks import import_feed

>>> import_feed.apply_async(args=['http://cnn.com/rss'],
...                           queue='feed_tasks',
...                           routing_key='feed.import')
```

To make server $z$ consume from the feed queue exclusively you can start it with the `celery worker -Q` option:

```
user@z://$ celery -A proj worker -Q feed_tasks --hostname=z@%h
```

Servers $x$ and $y$ must be configured to consume from the default queue:

```
user@x://$ celery -A proj worker -Q default --hostname=x@%h

user@y://$ celery -A proj worker -Q default --hostname=y@%h
```

If you want, you can even have your feed processing worker handle regular tasks as well, maybe in times when there’s a lot of work to do:

```
user@z://$ celery -A proj worker -Q feed_tasks,default --hostname=z@%h
```

If you have another queue but on another exchange you want to add, just specify a custom exchange and exchange type:

```
from kombu import Exchange, Queue

app.conf.task_queues = {
    Queue('feed_tasks', routing_key='feed.#'),
    Queue('regular_tasks', routing_key='task.#'),
}
```
If you’re confused about these terms, you should read up on AMQP.

See also:

In addition to the Redis Message Priorities below, there’s Rabbits and Warrens, an excellent blog post describing queues and exchanges. There’s also the CloudAMQP tutorial. For users of RabbitMQ the RabbitMQ FAQ could be useful as a source of information.

Special Routing Options

RabbitMQ Message Priorities

    supported transports  RabbitMQ

New in version 4.0.

Queues can be configured to support priorities by setting the `x-max-priority` argument:

```python
from kombu import Exchange, Queue

app.conf.task_queues = [
    Queue('tasks', Exchange('tasks'), routing_key='tasks',
          queue_arguments={'x-max-priority': 10}),
]
```

A default value for all queues can be set using the `task_queue_max_priority` setting:

```python
app.conf.task_queue_max_priority = 10
```

A default priority for all tasks can also be specified using the `task_default_priority` setting:

```python
app.conf.task_default_priority = 5
```

Redis Message Priorities

    supported transports  Redis

While the Celery Redis transport does honor the priority field, Redis itself has no notion of priorities. Please read this note before attempting to implement priorities with Redis as you may experience some unexpected behavior.

The priority support is implemented by creating n lists for each queue. This means that even though there are 10 (0-9) priority levels, these are consolidated into 4 levels by default to save resources. This means that a queue named celery will really be split into 4 queues:

```python
['celery0', 'celery3', 'celery6', 'celery9']
```

If you want more priority levels you can set the `priority_steps` transport option:

```python
app.conf.broker_transport_options = {
    'priority_steps': list(range(10)),
}
```
That said, note that this will never be as good as priorities implemented at the server level, and may be approximate at best. But it may still be good enough for your application.

**AMQP Primer**

**Messages**

A message consists of headers and a body. Celery uses headers to store the content type of the message and its content encoding. The content type is usually the serialization format used to serialize the message. The body contains the name of the task to execute, the task id (UUID), the arguments to apply it with and some additional meta-data – like the number of retries or an ETA.

This is an example task message represented as a Python dictionary:

```python
dict = {'task': 'myapp.tasks.add',
       'id': '54086c5e-6193-4575-8308-dbab76798756',
       'args': [4, 4],
       'kwargs': {}}
```

**Producers, consumers, and brokers**

The client sending messages is typically called a *publisher*, or a *producer*, while the entity receiving messages is called a *consumer*.

The *broker* is the message server, routing messages from producers to consumers.

You’re likely to see these terms used a lot in AMQP related material.

**Exchanges, queues, and routing keys**

1. Messages are sent to exchanges.
2. An exchange routes messages to one or more queues. Several exchange types exist, providing different ways to do routing, or implementing different messaging scenarios.
3. The message waits in the queue until someone consumes it.
4. The message is deleted from the queue when it has been acknowledged.

The steps required to send and receive messages are:

1. Create an exchange
2. Create a queue
3. Bind the queue to the exchange.

Celery automatically creates the entities necessary for the queues in `task_queues` to work (except if the queue’s `auto_declare` setting is set to `False`).

Here’s an example queue configuration with three queues; One for video, one for images, and one default queue for everything else:

```python
from kombu import Exchange, Queue

app.conf.task_queues = [
    Queue('default', Exchange('default'), routing_key='default'),
    Queue('video', Exchange('video'), routing_key='video'),
    Queue('images', Exchange('images'), routing_key='images'),
]  # (continues on next page)
```
Queue('videos', Exchange('media'), routing_key='media.video'),
Queue('images', Exchange('media'), routing_key='media.image'),
}  
app.conf.task_default_queue = 'default'
app.conf.task_default_exchange_type = 'direct'
app.conf.task_default_routing_key = 'default'

Exchange types

The exchange type defines how the messages are routed through the exchange. The exchange types defined in the standard are direct, topic, fanout and headers. Also non-standard exchange types are available as plug-ins to RabbitMQ, like the last-value-cache plug-in by Michael Bridgen.

Direct exchanges

Direct exchanges match by exact routing keys, so a queue bound by the routing key video only receives messages with that routing key.

Topic exchanges

Topic exchanges matches routing keys using dot-separated words, and the wild-card characters: * (matches a single word), and # (matches zero or more words).

With routing keys like usa.news, usa.weather, norway.news, and norway.weather, bindings could be *.news (all news), usa.# (all items in the USA), or usa.weather (all USA weather items).

Related API commands

exchange.declare(exchange_name, type, passive, durable, auto_delete, internal)
Declares an exchange by name.
See amqp:Channel.exchange_declare.

Keyword Arguments

• passive – Passive means the exchange won’t be created, but you can use this to check if the exchange already exists.
• durable – Durable exchanges are persistent (i.e., they survive a broker restart).
• auto_delete – This means the exchange will be deleted by the broker when there are no more queues using it.

queue.declare(queue_name, passive, durable, exclusive, auto_delete)
Declares a queue by name.
See amqp:Channel.queue_declare

Exclusive queues can only be consumed from by the current connection. Exclusive also implies auto_delete.
queue.bind(queue_name, exchange_name, routing_key)
    Binds a queue to an exchange with a routing key.

    Unbound queues won’t receive messages, so this is necessary.

    See amqp:Channel.queue_bind

queue.delete(name, if_unused=False, if_empty=False)
    Deletes a queue and its binding.

    See amqp:Channel.queue_delete

exchange.delete(name, if_unused=False)
    Deletes an exchange.

    See amqp:Channel.exchange_delete

**Note:** Declaring doesn’t necessarily mean “create”. When you declare you *assert* that the entity exists and that
it’s operable. There’s no rule as to whom should initially create the exchange/queue/binding, whether consumer or
producer. Usually the first one to need it will be the one to create it.

## Hands-on with the API

Celery comes with a tool called **celery amqp** that’s used for command line access to the AMQP API, enabling
access to administration tasks like creating/deleting queues and exchanges, purging queues or sending messages. It
can also be used for non-AMQP brokers, but different implementation may not implement all commands.

You can write commands directly in the arguments to **celery amqp**, or just start with no arguments to start it in
shell-mode:

```
$ celery -A proj amqp
-> connecting to amqp://guest@localhost:5672/.
-> connected.
1>
```

Here 1> is the prompt. The number 1, is the number of commands you have executed so far. Type `help` for a list of
commands available. It also supports auto-completion, so you can start typing a command and then hit the `tab` key to
show a list of possible matches.

Let’s create a queue you can send messages to:

```
$ celery -A proj amqp
1> exchange.declare testexchange direct
ok.
2> queue.declare testqueue
ok. queue:testqueue messages:0 consumers:0.
3> queue.bind testqueue testexchange testkey
ok.
```

This created the direct exchange `testexchange`, and a queue named `testqueue`. The queue is bound to the
exchange using the routing key `testkey`.

From now on all messages sent to the exchange `testexchange` with routing key `testkey` will be moved to this
queue. You can send a message by using the `basic.publish` command:

```
1> basic.publish 'This is a message!' testexchange testkey
ok.
```
Now that the message is sent you can retrieve it again. You can use the `basic.get` command here, that polls for new messages on the queue in a synchronous manner (this is OK for maintenance tasks, but for services you want to use `basic.consume` instead)

Pop a message off the queue:

```
5> basic.get testqueue
{'body': 'This is a message!',
 'delivery_info': {'delivery_tag': 1,
  'exchange': u'testexchange',
  'message_count': 0,
  'redelivered': False,
  'routing_key': u'testkey'},
 'properties': {}}
```

AMQP uses acknowledgment to signify that a message has been received and processed successfully. If the message hasn’t been acknowledged and consumer channel is closed, the message will be delivered to another consumer.

Note the delivery tag listed in the structure above; Within a connection channel, every received message has a unique delivery tag. This tag is used to acknowledge the message. Also note that delivery tags aren’t unique across connections, so in another client the delivery tag 1 might point to a different message than in this channel.

You can acknowledge the message you received using `basic.ack`:

```
6> basic.ack 1
ok.
```

To clean up after our test session you should delete the entities you created:

```
7> queue.delete testqueue
ok. 0 messages deleted.
8> exchange.delete testexchange
ok.
```

**Routing Tasks**

**Defining queues**

In Celery available queues are defined by the `task_queues` setting.

Here’s an example queue configuration with three queues; One for video, one for images, and one default queue for everything else:

```
default_exchange = Exchange('default', type='direct')
media_exchange = Exchange('media', type='direct')

app.conf.task_queues = {
    Queue('default', default_exchange, routing_key='default'),
    Queue('videos', media_exchange, routing_key='media.video'),
    Queue('images', media_exchange, routing_key='media.image')
}
```

Here, the `task_default_queue` will be used to route tasks that doesn’t have an explicit route.
The default exchange, exchange type, and routing key will be used as the default routing values for tasks, and as the default values for entries in `task_queues`.

Multiple bindings to a single queue are also supported. Here’s an example of two routing keys that are both bound to the same queue:

```python
from kombu import Exchange, Queue, binding
media_exchange = Exchange('media', type='direct')

CELERY_QUEUES = (  
    Queue('media', [  
        binding(media_exchange, routing_key='media.video'),  
        binding(media_exchange, routing_key='media.image'),  
    ]),
)
```

### Specifying task destination

The destination for a task is decided by the following (in order):

1. The routing arguments to `Task.apply_async()`.
2. Routing related attributes defined on the `Task` itself.
3. The `Routers` defined in `task_routes`.

It’s considered best practice to not hard-code these settings, but rather leave that as configuration options by using `Routers`; This is the most flexible approach, but sensible defaults can still be set as task attributes.

### Routers

A router is a function that decides the routing options for a task.

All you need to define a new router is to define a function with the signature `(name, args, kwargs, options, task=None, **kw)`:  

```python
def route_task(name, args, kwargs, options, task=None, **kw):
    if name == 'myapp.tasks.compress_video':
        return {'exchange': 'video',
                'exchange_type': 'topic',
                'routing_key': 'video.compress'}
```

If you return the `queue` key, it’ll expand with the defined settings of that queue in `task_queues`:

```python
{'queue': 'video', 'routing_key': 'video.compress'}
```

becomes →

```python
{'queue': 'video',  
 'exchange': 'video',
 'exchange_type': 'topic',
 'routing_key': 'video.compress'}
```

You install router classes by adding them to the `task_routes` setting:
Router functions can also be added by name:

```
(task_routes = ('myapp.routers.route_task',))
```

For simple task name -> route mappings like the router example above, you can simply drop a dict into `task_routes` to get the same behavior:

```
(task_routes = {
    'myapp.tasks.compress_video': {
        'queue': 'video',
        'routing_key': 'video.compress',
    },
})
```

The routers will then be traversed in order, it will stop at the first router returning a true value, and use that as the final route for the task.

You can also have multiple routers defined in a sequence:

```
(task_routes = [
    route_task,
    {
        'myapp.tasks.compress_video': {
            'queue': 'video',
            'routing_key': 'video.compress',
        },
    }]
```

The routers will then be visited in turn, and the first to return a value will be chosen.

If you're using Redis or RabbitMQ you can also specify the queue's default priority in the route.

```
(task_routes = {
    'myapp.tasks.compress_video': {
        'queue': 'video',
        'routing_key': 'video.compress',
        'priority': 10,
    },
})
```

Similarly, calling `apply_async` on a task will override that default priority.

```
task.apply_async(priority=0)
```

**Priority Order and Cluster Responsiveness**

It is important to note that, due to worker prefetching, if a bunch of tasks submitted at the same time they may be out of priority order at first. Disabling worker prefetching will prevent this issue, but may cause less than ideal performance for small, fast tasks. In most cases, simply reducing `worker_prefetch_multiplier` to 1 is an easier and cleaner way to increase the responsiveness of your system without the costs of disabling prefetching entirely.

Note that priorities values are sorted in reverse when using the redis broker: 0 being highest priority.
Broadcast

Celery can also support broadcast routing. Here is an example exchange `broadcast_tasks` that delivers copies of tasks to all workers connected to it:

```python
from kombu.common import Broadcast

app.conf.task_queues = (Broadcast('broadcast_tasks'),)
app.conf.task_routes = {
    'tasks.reload_cache': {
        'queue': 'broadcast_tasks',
        'exchange': 'broadcast_tasks'
    }
}
```

Now the `tasks.reload_cache` task will be sent to every worker consuming from this queue.

Here is another example of broadcast routing, this time with a `celery beat` schedule:

```python
from kombu.common import Broadcast
from celery.schedules import crontab

app.conf.task_queues = (Broadcast('broadcast_tasks'),)

app.conf.beat_schedule = {
    'test-task': {
        'task': 'tasks.reload_cache',
        'schedule': crontab(minute=0, hour='*/3'),
        'options': {'exchange': 'broadcast_tasks'}
    },
}
```

Broadcast & Results

Note that Celery result doesn’t define what happens if two tasks have the same task_id. If the same task is distributed to more than one worker, then the state history may not be preserved.

It’s a good idea to set the `task.ignore_result` attribute in this case.

3.3.9 Monitoring and Management Guide

- **Introduction**
- **Workers**
  - Management Command-line Utilities (`inspect/control`)
    - Commands
    - Specifying destination nodes
  - Flower: Real-time Celery web-monitor
    - Features
    - Usage
Introduction

There are several tools available to monitor and inspect Celery clusters. This document describes some of these, as well as features related to monitoring, like events and broadcast commands.

Workers

Management Command-line Utilities (inspect/control)

celery can also be used to inspect and manage worker nodes (and to some degree tasks).

To list all the commands available do:
Celery Documentation, Release 4.4.0

$ celery help

or to get help for a specific command do:

$ celery <command> --help

**Commands**

- **shell**: Drop into a Python shell.
  The locals will include the `celery` variable: this is the current app. Also all known tasks will be automatically added to locals (unless the `--without-tasks` flag is set).
  Uses Ipython, bpython, or regular `python` in that order if installed. You can force an implementation using `--ipython`, `--bpython`, or `--python`.

- **status**: List active nodes in this cluster
  
  $ celery -A proj status

- **result**: Show the result of a task
  
  $ celery -A proj result -t tasks.add 4e196aa4-0141-4601-8138-7aa33db0f577
  
  Note that you can omit the name of the task as long as the task doesn’t use a custom result backend.

- **purge**: Purge messages from all configured task queues.
  This command will remove all messages from queues configured in the `CELERY_QUEUES` setting:

  **Warning**: There’s no undo for this operation, and messages will be permanently deleted!

  $ celery -A proj purge
  
  You can also specify the queues to purge using the `-Q` option:

  $ celery -A proj purge -Q celery,foo,bar
  
  and exclude queues from being purged using the `-X` option:

  $ celery -A proj purge -X celery

- **inspect active**: List active tasks
  
  $ celery -A proj inspect active
  
  These are all the tasks that are currently being executed.

- **inspect scheduled**: List scheduled ETA tasks
  
  $ celery -A proj inspect scheduled
  
  These are tasks reserved by the worker when they have an `eta` or `countdown` argument set.

- **inspect reserved**: List reserved tasks
$ celery -A proj inspect reserved

This will list all tasks that have been prefetched by the worker, and is currently waiting to be executed (doesn’t include tasks with an ETA value set).

- **inspect revoked**: List history of revoked tasks
  $ celery -A proj inspect revoked

- **inspect registered**: List registered tasks
  $ celery -A proj inspect registered

- **inspect stats**: Show worker statistics (see Statistics)
  $ celery -A proj inspect stats

- **inspect query_task**: Show information about task(s) by id.
  Any worker having a task in this set of ids reserved/active will respond with status and information.
  $ celery -A proj inspect query_task e9f6c8f0-fec9-4ae8-a8c6-cf8c8451d4f8

  You can also query for information about multiple tasks:
  $ celery -A proj inspect query_task id1 id2 ... idN

- **control enable_events**: Enable events
  $ celery -A proj control enable_events

- **control disable_events**: Disable events
  $ celery -A proj control disable_events

- **migrate**: Migrate tasks from one broker to another (EXPERIMENTAL).
  $ celery -A proj migrate redis://localhost amqp://localhost

  This command will migrate all the tasks on one broker to another. As this command is new and experimental you should be sure to have a backup of the data before proceeding.

**Note**: All inspect and control commands supports a **--timeout** argument. This is the number of seconds to wait for responses. You may have to increase this timeout if you’re not getting a response due to latency.

### Specifying destination nodes

By default the inspect and control commands operates on all workers. You can specify a single, or a list of workers by using the **--destination** argument:

$ celery -A proj inspect -d w1@e.com,w2@e.com reserved

$ celery -A proj control -d w1@e.com,w2@e.com enable_events

---

3.3. User Guide
**Flower: Real-time Celery web-monitor**

Flower is a real-time web based monitor and administration tool for Celery. It’s under active development, but is already an essential tool. Being the recommended monitor for Celery, it obsoletes the Django-Admin monitor, `celerymon` and the `ncurses` based monitor.

Flower is pronounced like “flow”, but you can also use the botanical version if you prefer.

**Features**

- Real-time monitoring using Celery Events
  - Task progress and history
  - Ability to show task details (arguments, start time, run-time, and more)
  - Graphs and statistics
- Remote Control
  - View worker status and statistics
  - Shutdown and restart worker instances
  - Control worker pool size and autoscale settings
  - View and modify the queues a worker instance consumes from
  - View currently running tasks
  - View scheduled tasks (ETA/countdown)
  - View reserved and revoked tasks
  - Apply time and rate limits
  - Configuration viewer
  - Revoke or terminate tasks
- HTTP API
  - List workers
  - Shut down a worker
  - Restart worker’s pool
  - Grow worker’s pool
  - Shrink worker’s pool
  - Autoscale worker pool
  - Start consuming from a queue
  - Stop consuming from a queue
  - List tasks
  - List (seen) task types
  - Get a task info
  - Execute a task
  - Execute a task by name
– Get a task result
– Change soft and hard time limits for a task
– Change rate limit for a task
– Revoke a task

• OpenID authentication

Usage

You can use pip to install Flower:

```
$ pip install flower
```

Running the flower command will start a web-server that you can visit:

```
$ celery -A proj flower
```

The default port is http://localhost:5555, but you can change this using the --port argument:
Broker URL can also be passed through the `--broker` argument:

```
celery flower --broker=amqp://guest:guest@localhost:5672/
```

or

```
celery flower --broker=redis://guest:guest@localhost:6379/0
```

Then, you can visit flower in your web browser:

```
open http://localhost:5555
```

Flower has many more features than are detailed here, including authorization options. Check out the official documentation for more information.

**celery events: Curses Monitor**

New in version 2.0.

`celery events` is a simple curses monitor displaying task and worker history. You can inspect the result and traceback of tasks, and it also supports some management commands like rate limiting and shutting down workers. This monitor was started as a proof of concept, and you probably want to use Flower instead.

Starting:

```
celery -A proj events
```
<table>
<thead>
<tr>

You should see a screen like:

`celery events` is also used to start snapshot cameras (see Snapshots):

```
$ celery -A proj events --camera=<camera-class> --frequency=1.0
```

and it includes a tool to dump events to stdout:

```
$ celery -A proj events --dump
```

For a complete list of options use `--help`:

```
$ celery events --help
```

**RabbitMQ**

To manage a Celery cluster it is important to know how RabbitMQ can be monitored.

RabbitMQ ships with the `rabbitmqctl(1)` command, with this you can list queues, exchanges, bindings, queue lengths, the memory usage of each queue, as well as manage users, virtual hosts and their permissions.

**Note:** The default virtual host ("/") is used in these examples, if you use a custom virtual host you have to add the `-p` argument to the command, for example: `rabbitmqctl list_queues -p my_vhost ...

**Inspecting queues**

Finding the number of tasks in a queue:

```
$ rabbitmqctl list_queues name messages messages_ready \
   messages_unacknowledged
```

Here `messages_ready` is the number of messages ready for delivery (sent but not received), `messages_unacknowledged` is the number of messages that’s been received by a worker but not acknowledged yet (meaning it is in progress, or has been reserved). `messages` is the sum of ready and unacknowledged messages.

Finding the number of workers currently consuming from a queue:

```
$ rabbitmqctl list_queues name consumers
```

Finding the amount of memory allocated to a queue:

```
$ rabbitmqctl list_queues name memory
```

**Tip** Adding the `-q` option to `rabbitmqctl(1)` makes the output easier to parse.

**Redis**

If you’re using Redis as the broker, you can monitor the Celery cluster using the `redis-cli(1)` command to list lengths of queues.
Inspecting queues

Finding the number of tasks in a queue:

```
$ redis-cli -h HOST -p PORT -n DATABASE_NUMBER llen QUEUE_NAME
```

The default queue is named `celery`. To get all available queues, invoke:

```
$ redis-cli -h HOST -p PORT -n DATABASE_NUMBER keys *
```

**Note:** Queue keys only exists when there are tasks in them, so if a key doesn’t exist it simply means there are no messages in that queue. This is because in Redis a list with no elements in it is automatically removed, and hence it won’t show up in the `keys` command output, and `llen` for that list returns 0.

Also, if you’re using Redis for other purposes, the output of the `keys` command will include unrelated values stored in the database. The recommended way around this is to use a dedicated `DATABASE_NUMBER` for Celery, you can also use database numbers to separate Celery applications from each other (virtual hosts), but this won’t affect the monitoring events used by for example Flower as Redis pub/sub commands are global rather than database based.

Munin

This is a list of known Munin plug-ins that can be useful when maintaining a Celery cluster.

- `rabbitmq-munin`: Munin plug-ins for RabbitMQ.
  
  https://github.com/ask/rabbitmq-munin

- `celery_tasks`: Monitors the number of times each task type has been executed (requires `celerymon`).
  

- `celery_tasks_states`: Monitors the number of tasks in each state (requires `celerymon`).
  
  https://github.com/munin-monitoring/contrib/blob/master/plugins/celery/celery_tasks_states

Events

The worker has the ability to send a message whenever some event happens. These events are then captured by tools like Flower, and `celery events` to monitor the cluster.

Snapshots

New in version 2.1.

Even a single worker can produce a huge amount of events, so storing the history of all events on disk may be very expensive.

A sequence of events describes the cluster state in that time period, by taking periodic snapshots of this state you can keep all history, but still only periodically write it to disk.

To take snapshots you need a Camera class, with this you can define what should happen every time the state is captured; You can write it to a database, send it by email or something else entirely.

`celery events` is then used to take snapshots with the camera, for example if you want to capture state every 2 seconds using the camera `myapp.Camera` you run `celery events` with the following arguments:
Celery Documentation, Release 4.4.0

Custom Camera

Cameras can be useful if you need to capture events and do something with those events at an interval. For real-time event processing you should use `app.events.Receiver` directly, like in Real-time processing.

Here is an example camera, dumping the snapshot to screen:

```python
from pprint import pformat
from celery.events.snapshot import Polaroid

class DumpCam(Polaroid):
    clear_after = True  # clear after flush (incl, state.event_count).

    def on_shutter(self, state):
        if not state.event_count:
            # No new events since last snapshot.
            return
        print('Workers: {}'.format(pformat(state.workers, indent=4)))
        print('Tasks: {}'.format(pformat(state.tasks, indent=4)))
        print('Total: {0.event_count} events, {0.task_count} tasks'.format(state))

See the API reference for `celery.events.state` to read more about state objects.

Now you can use this cam with celery events by specifying it with the `-c` option:

```bash
$ celery -A proj events -c myapp.DumpCam --frequency=2.0
```

Or you can use it programmatically like this:

```python
from celery import Celery
from myapp import DumpCam

def main(app, freq=1.0):
    state = app.events.State()
    with app.connection() as connection:
        recv = app.events.Receiver(connection, handlers={'*': state.event})
    with DumpCam(state, freq=freq):
        recv.capture(limit=None, timeout=None)

if __name__ == '__main__':
    app = Celery(broker='amqp://guest@localhost//')
    main(app)
```

Real-time processing

To process events in real-time you need the following

- An event consumer (this is the Receiver)
- A set of handlers called when events come in.

You can have different handlers for each event type, or a catch-all handler can be used (`'*'`)
• State (optional)

    app.events.State is a convenient in-memory representation of tasks and workers in the cluster that’s updated as events come in.

    It encapsulates solutions for many common things, like checking if a worker is still alive (by verifying heartbeats), merging event fields together as events come in, making sure time-stamps are in sync, and so on.

Combining these you can easily process events in real-time:

```python
from celery import Celery

def my_monitor(app):
    state = app.events.State()

    def announce_failed_tasks(event):
        state.event(event)
        # task name is sent only with -received event, and state
        # will keep track of this for us.
        task = state.tasks.get(event['uuid'])

        print('TASK FAILED: %s [%s] %s' %
              (task.name, task.uuid, task.info(),))

    with app.connection() as connection:
        recv = app.events.Receiver(connection, handlers={
            'task-failed': announce_failed_tasks,
            '*': state.event,
        })
        recv.capture(limit=None, timeout=None, wakeup=True)

if __name__ == '__main__':
    app = Celery(broker='amqp://guest@localhost//')
    my_monitor(app)
```

**Note:** The `wakeup` argument to `capture` sends a signal to all workers to force them to send a heartbeat. This way you can immediately see workers when the monitor starts.

You can listen to specific events by specifying the handlers:

```python
from celery import Celery

def my_monitor(app):
    state = app.events.State()

    def announce_failed_tasks(event):
        state.event(event)
        # task name is sent only with -received event, and state
        # will keep track of this for us.
        task = state.tasks.get(event['uuid'])

        print('TASK FAILED: %s [%s] %s' %
              (task.name, task.uuid, task.info(),))

    with app.connection() as connection:
        recv = app.events.Receiver(connection, handlers={
            ...
        })

(continues on next page)```
Event Reference

This list contains the events sent by the worker, and their arguments.

Task Events

task-sent

- **signature** task-sent(uuid, name, args, kwargs, retries, eta, expires, queue, exchange, routing_key, root_id, parent_id)

  Sent when a task message is published and the `task_send_sent_event` setting is enabled.

task-received

- **signature** task-received(uuid, name, args, kwargs, retries, eta, hostname, timestamp, root_id, parent_id)

  Sent when the worker receives a task.

task-started

- **signature** task-started(uuid, hostname, timestamp, pid)

  Sent just before the worker executes the task.

task-succeeded

- **signature** task-succeeded(uuid, result, runtime, hostname, timestamp)

  Sent if the task executed successfully.

  Run-time is the time it took to execute the task using the pool. (Starting from the task is sent to the worker pool, and ending when the pool result handler callback is called).

task-failed

- **signature** task-failed(uuid, exception, traceback, hostname, timestamp)

  Sent if the execution of the task failed.
**task-rejected**

**signature** `task-rejected(uuid, requeued)`

The task was rejected by the worker, possibly to be re-queued or moved to a dead letter queue.

**task-revoked**

**signature** `task-revoked(uuid, terminated, signum, expired)`

Sent if the task has been revoked (Note that this is likely to be sent by more than one worker).

- `terminated` is set to true if the task process was terminated, and the `signum` field set to the signal used.
- `expired` is set to true if the task expired.

**task-retried**

**signature** `task-retried(uuid, exception, traceback, hostname, timestamp)`

Sent if the task failed, but will be retried in the future.

**Worker Events**

**worker-online**

**signature** `worker-online(hostname, timestamp, freq, sw_ident, sw_ver, sw_sys)`

The worker has connected to the broker and is online.

- `hostname`: Nodename of the worker.
- `timestamp`: Event time-stamp.
- `freq`: Heartbeat frequency in seconds (float).
- `sw_ident`: Name of worker software (e.g., py-celery).
- `sw_ver`: Software version (e.g., 2.2.0).
- `sw_sys`: Operating System (e.g., Linux/Darwin).

**worker-heartbeat**

**signature** `worker-heartbeat(hostname, timestamp, freq, sw_ident, sw_ver, sw_sys, active, processed)`

Sent every minute, if the worker hasn’t sent a heartbeat in 2 minutes, it is considered to be offline.

- `hostname`: Nodename of the worker.
- `timestamp`: Event time-stamp.
- `freq`: Heartbeat frequency in seconds (float).
- `sw_ident`: Name of worker software (e.g., py-celery).
• sw_ver: Software version (e.g., 2.2.0).
• sw_sys: Operating System (e.g., Linux/Darwin).
• active: Number of currently executing tasks.
• processed: Total number of tasks processed by this worker.

worker-offline

signature worker-offline(hostname, timestamp, freq, sw_ident, sw_ver, sw_sys)

The worker has disconnected from the broker.

3.3.10 Security

Introduction

While Celery is written with security in mind, it should be treated as an unsafe component. Depending on your Security Policy, there are various steps you can take to make your Celery installation more secure.

Areas of Concern

Broker

It’s imperative that the broker is guarded from unwanted access, especially if accessible to the public. By default, workers trust that the data they get from the broker hasn’t been tampered with. See Message Signing for information on how to make the broker connection more trustworthy.

The first line of defense should be to put a firewall in front of the broker, allowing only white-listed machines to access it.
Keep in mind that both firewall misconfiguration, and temporarily disabling the firewall, is common in the real world. Solid security policy includes monitoring of firewall equipment to detect if they’ve been disabled, be it accidentally or on purpose.

In other words, one shouldn’t blindly trust the firewall either.

If your broker supports fine-grained access control, like RabbitMQ, this is something you should look at enabling. See for example http://www.rabbitmq.com/access-control.html.

If supported by your broker backend, you can enable end-to-end SSL encryption and authentication using `broker_use_ssl`.

**Client**

In Celery, “client” refers to anything that sends messages to the broker, for example web-servers that apply tasks.

Having the broker properly secured doesn’t matter if arbitrary messages can be sent through a client.

[Need more text here]

**Worker**

The default permissions of tasks running inside a worker are the same ones as the privileges of the worker itself. This applies to resources, such as; memory, file-systems, and devices.

An exception to this rule is when using the multiprocessing based task pool, which is currently the default. In this case, the task will have access to any memory copied as a result of the `fork()` call, and access to memory contents written by parent tasks in the same worker child process.

Limiting access to memory contents can be done by launching every task in a subprocess (`fork()` + `execve()`).

Limiting file-system and device access can be accomplished by using chroot, jail, sandboxing, virtual machines, or other mechanisms as enabled by the platform or additional software.

Note also that any task executed in the worker will have the same network access as the machine on which it’s running. If the worker is located on an internal network it’s recommended to add firewall rules for outbound traffic.

**Serializers**

The default serializer is JSON since version 4.0, but since it has only support for a restricted set of types you may want to consider using pickle for serialization instead.

The `pickle` serializer is convenient as it can serialize almost any Python object, even functions with some work, but for the same reasons `pickle` is inherently insecure¹, and should be avoided whenever clients are untrusted or unauthenticated.

You can disable untrusted content by specifying a white-list of accepted content-types in the `accept_content` setting:

New in version 3.0.18.

**Note:** This setting was first supported in version 3.0.18. If you’re running an earlier version it will simply be ignored, so make sure you’re running a version that supports it.

¹ https://blog.nelhage.com/2011/03/exploiting-pickle/
accept_content = ['json']

This accepts a list of serializer names and content-types, so you could also specify the content type for json:

accept_content = ['application/json']

Celery also comes with a special auth serializer that validates communication between Celery clients and workers, making sure that messages originates from trusted sources. Using Public-key cryptography the auth serializer can verify the authenticity of senders, to enable this read Message Signing for more information.

## Message Signing

Celery can use the cryptography library to sign message using Public-key cryptography, where messages sent by clients are signed using a private key and then later verified by the worker using a public certificate. Optimally certificates should be signed by an official Certificate Authority, but they can also be self-signed.

To enable this you should configure the task_serializer setting to use the auth serializer. Enforcing the workers to only accept signed messages, you should set accept_content to ['auth']. For additional signing of the event protocol, set event_serializer to auth. Also required is configuring the paths used to locate private keys and certificates on the file-system: the security_key, security_certificate, and security_cert_store settings respectively. You can tweak the signing algorithm with security_digest.

With these configured it’s also necessary to call the celery.setup_security() function. Note that this will also disable all insecure serializers so that the worker won’t accept messages with untrusted content types.

This is an example configuration using the auth serializer, with the private key and certificate files located in /etc/ssl.

```python
app = Celery()
app.conf.update(
    security_key='/etc/ssl/private/worker.key',
    security_certificate='/etc/ssl/certs/worker.pem',
    security_cert_store='/etc/ssl/certs/*.pem',
    security_digest='sha256',
    task_serializer='auth',
    event_serializer='auth',
    accept_content=['auth'])
app.setup_security()
```

Note: While relative paths aren’t disallowed, using absolute paths is recommended for these files. Also note that the auth serializer won’t encrypt the contents of a message, so if needed this will have to be enabled separately.

## Intrusion Detection

The most important part when defending your systems against intruders is being able to detect if the system has been compromised.
Logs

Logs are usually the first place to look for evidence of security breaches, but they’re useless if they can be tampered with.

A good solution is to set up centralized logging with a dedicated logging server. Access to it should be restricted. In addition to having all of the logs in a single place, if configured correctly, it can make it harder for intruders to tamper with your logs.

This should be fairly easy to set up using syslog (see also syslog-ng and rsyslog). Celery uses the logging library, and already has support for using syslog.

A tip for the paranoid is to send logs using UDP and cut the transmit part of the logging server’s network cable :-)

Tripwire

Tripwire is a (now commercial) data integrity tool, with several open source implementations, used to keep cryptographic hashes of files in the file-system, so that administrators can be alerted when they change. This way when the damage is done and your system has been compromised you can tell exactly what files intruders have changed (password files, logs, back-doors, root-kits, and so on). Often this is the only way you’ll be able to detect an intrusion.

Some open source implementations include:

- OSSEC
- Samhain
- Open Source Tripwire
- AIDE

Also, the ZFS file-system comes with built-in integrity checks that can be used.

3.3.11 Optimizing

Introduction

The default configuration makes a lot of compromises. It’s not optimal for any single case, but works well enough for most situations.

There are optimizations that can be applied based on specific use cases.

Optimizations can apply to different properties of the running environment, be it the time tasks take to execute, the amount of memory used, or responsiveness at times of high load.

Ensuring Operations

In the book Programming Pearls, Jon Bentley presents the concept of back-of-the-envelope calculations by asking the question:

How much water flows out of the Mississippi River in a day?

The point of this exercise\(^0\) is to show that there’s a limit to how much data a system can process in a timely manner. Back of the envelope calculations can be used as a means to plan for this ahead of time.

\(^0\) The chapter is available to read for free here: The back of the envelope. The book is a classic text. Highly recommended.
In Celery, if a task takes 10 minutes to complete, and there are 10 new tasks coming in every minute, the queue will never be empty. This is why it’s very important that you monitor queue lengths!

A way to do this is by using Munin. You should set up alerts, that’ll notify you as soon as any queue has reached an unacceptable size. This way you can take appropriate action like adding new worker nodes, or revoking unnecessary tasks.

**General Settings**

**Broker Connection Pools**

The broker connection pool is enabled by default since version 2.5.

You can tweak the `broker_pool_limit` setting to minimize contention, and the value should be based on the number of active threads/green-threads using broker connections.

**Using Transient Queues**

Queues created by Celery are persistent by default. This means that the broker will write messages to disk to ensure that the tasks will be executed even if the broker is restarted.

But in some cases it’s fine that the message is lost, so not all tasks require durability. You can create a transient queue for these tasks to improve performance:

```python
from kombu import Exchange, Queue

task_queues = (  
    Queue('celery', routing_key='celery'),  
    Queue('transient', Exchange('transient', delivery_mode=1),  
          routing_key='transient', durable=False),  
)
```

or by using `task_routes`:

```python
task_routes = {  
    'proj.tasks.add': {  
          'queue': 'celery',  
          'delivery_mode': 'transient',  
    }  
}
```

The `delivery_mode` changes how the messages to this queue are delivered. A value of one means that the message won’t be written to disk, and a value of two (default) means that the message can be written to disk.

To direct a task to your new transient queue you can specify the queue argument (or use the `task_routes` setting):

```python
task.apply_async(args, queue='transient')
```

For more information see the routing guide.

**Worker Settings**

**Prefetch Limits**

`Prefetch` is a term inherited from AMQP that’s often misunderstood by users.
The prefetch limit is a **limit** for the number of tasks (messages) a worker can reserve for itself. If it is zero, the worker will keep consuming messages, not respecting that there may be other available worker nodes that may be able to process them sooner\(^0\), or that the messages may not even fit in memory.

The workers’ default prefetch count is the `worker_prefetch_multiplier` setting multiplied by the number of concurrency slots\(^1\) (processes/threads/green-threads).

If you have many tasks with a long duration you want the multiplier value to be *one*: meaning it’ll only reserve one task per worker process at a time.

However – If you have many short-running tasks, and throughput/round trip latency is important to you, this number should be large. The worker is able to process more tasks per second if the messages have already been prefetched, and is available in memory. You may have to experiment to find the best value that works for you. Values like 50 or 150 might make sense in these circumstances. Say 64, or 128.

If you have a combination of long- and short-running tasks, the best option is to use two worker nodes that are configured separately, and route the tasks according to the run-time (see *Routing Tasks*).

### Reserve one task at a time

The task message is only deleted from the queue after the task is acknowledged, so if the worker crashes before acknowledging the task, it can be redelivered to another worker (or the same after recovery).

When using the default of early acknowledgment, having a prefetch multiplier setting of *one*, means the worker will reserve at most one extra task for every worker process: or in other words, if the worker is started with `-c 10`, the worker may reserve at most 20 tasks (10 acknowledged tasks executing, and 10 unacknowledged reserved tasks) at any time.

Often users ask if disabling “prefetching of tasks” is possible, but what they really mean by that, is to have a worker only reserve as many tasks as there are worker processes (10 unacknowledged tasks for `-c 10`).

That’s possible, but not without also enabling *late acknowledgment*. Using this option over the default behavior means a task that’s already started executing will be retried in the event of a power failure or the worker instance being killed abruptly, so this also means the task must be **idempotent**

**See also:**

Notes at *Should I use retry or acks_late?*.

You can enable this behavior by using the following configuration options:

```python
#task_acks_late = True
worker_prefetch_multiplier = 1
```

### Prefork pool prefetch settings

The prefork pool will asynchronously send as many tasks to the processes as it can and this means that the processes are, in effect, prefetching tasks.

This benefits performance but it also means that tasks may be stuck waiting for long running tasks to complete:

\(^0\) RabbitMQ and other brokers deliver messages round-robin, so this doesn’t apply to an active system. If there’s no prefetch limit and you restart the cluster, there will be timing delays between nodes starting. If there are 3 offline nodes and one active node, all messages will be delivered to the active node.

\(^1\) This is the concurrency setting; `worker_concurrency` or the `celery worker -c` option.
The worker will send tasks to the process as long as the pipe buffer is writable. The pipe buffer size varies based on the operating system: some may have a buffer as small as 64KB but on recent Linux versions the buffer size is 1MB (can only be changed system wide).

You can disable this prefetching behavior by enabling the `-O fair` worker option:

```
$ celery -A proj worker -l info -O fair
```

With this option enabled the worker will only write to processes that are available for work, disabling the prefetch behavior:

```
--> send task T1 to process A
    # A executes T1
--> send task T2 to process B
    # B executes T2
<- T2 complete sent by process B

--> send task T3 to process A
    # A still executing T1, T3 stuck in local buffer and won't start until
    # T1 returns, and other queued tasks won't be sent to idle processes
<- T1 complete sent by process A
    # A executes T3
<- T3 complete sent by process B
<- T1 complete sent by process A
```

### 3.3.12 Debugging

#### Debugging Tasks Remotely (using pdb)

**Basics**

`celery.contrib.rdb` is an extended version of `pdb` that enables remote debugging of processes that doesn’t have terminal access.

Example usage:

```python
from celery import task
from celery.contrib import rdb

@task()
def add(x, y):
    result = x + y
    rdb.set_trace()  # <- set break-point
    return result
```
**set_trace()** sets a break-point at the current location and creates a socket you can telnet into to remotely debug your task.

The debugger may be started by multiple processes at the same time, so rather than using a fixed port the debugger will search for an available port, starting from the base port (6900 by default). The base port can be changed using the environment variable **CELERY_RDB_PORT**.

By default the debugger will only be available from the local host, to enable access from the outside you have to set the environment variable **CELERY_RDB_HOST**.

When the worker encounters your break-point it’ll log the following information:

```
[INFO/MainProcess] Received task: tasks.add[d7261c71-4962-47e5-b342-2448bedd20e8]
[WARNING/PoolWorker-1] Remote Debugger:6900:
  Please telnet 127.0.0.1 6900. Type 'exit' in session to continue.
  Waiting for client...
```

If you telnet the port specified you’ll be presented with a **pdb** shell:

```bash
$ telnet localhost 6900
Connected to localhost.
Escape character is '^]'.
> /opt/devel/demoapp/tasks.py(128)add()
--> return result
(Pdb)
```

Enter **help** to get a list of available commands. It may be a good idea to read the [Python Debugger Manual](http://docs.python.org/library/pdb.html) if you have never used **pdb** before.

To demonstrate, we’ll read the value of the **result** variable, change it and continue execution of the task:

```
(Pdb) result
4
(Pdb) result = 'hello from rdb'
(Pdb) continue
```

The result of our vandalism can be seen in the worker logs:

```
tasks.add[d7261c71-4962-47e5-b342-2448bedd20e8] succeeded
in 61.481s: 'hello from rdb'
```

**Tips**

**Enabling the break-point signal**

If the environment variable **CELERY_RDBSIG** is set, the worker will open up an rdb instance whenever the **SIGUSR2** signal is sent. This is the case for both main and worker processes.

For example starting the worker with:

```
$ CELERY_RDBSIG=1 celery worker -l info
```

You can start an rdb session for any of the worker processes by executing:
3.3.13 Concurrency

Release  4.4  
Date  Dec 16, 2019

Concurrency with Eventlet

Introduction

The Eventlet homepage describes it as a concurrent networking library for Python that allows you to change how you run your code, not how you write it.

- It uses epoll(4) or libevent for highly scalable non-blocking I/O.
- Coroutines ensure that the developer uses a blocking style of programming that’s similar to threading, but provide the benefits of non-blocking I/O.
- The event dispatch is implicit: meaning you can easily use Eventlet from the Python interpreter, or as a small part of a larger application.

Celery supports Eventlet as an alternative execution pool implementation and in some cases superior to prefork. However, you need to ensure one task doesn’t block the event loop too long. Generally, CPU-bound operations don’t go well with Eventlet. Also note that some libraries, usually with C extensions, cannot be monkeypatched and therefore cannot benefit from using Eventlet. Please refer to their documentation if you are not sure. For example, pylibmc does not allow cooperation with Eventlet but psycopg2 does when both of them are libraries with C extensions.

The prefork pool can take use of multiple processes, but how many is often limited to a few processes per CPU. With Eventlet you can efficiently spawn hundreds, or thousands of green threads. In an informal test with a feed hub system the Eventlet pool could fetch and process hundreds of feeds every second, while the prefork pool spent 14 seconds processing 100 feeds. Note that this is one of the applications async I/O is especially good at (asynchronous HTTP requests). You may want a mix of both Eventlet and prefork workers, and route tasks according to compatibility or what works best.

Enabling Eventlet

You can enable the Eventlet pool by using the celery worker -P worker option.

```
$ celery -A proj worker -P eventlet -c 1000
```

Examples

See the Eventlet examples directory in the Celery distribution for some examples taking use of Eventlet support.

3.3.14 Signals
• Basics
• Signals
  – Task Signals
    • before_task_publish
    • after_task_publish
    • task_prerun
    • task_postrun
    • task_retry
    • task_success
    • task_failure
    • task_received
    • task_revoked
    • task_unknown
    • task_rejected
  – App Signals
    • import_modules
  – Worker Signals
    • celeryd_after_setup
    • celeryd_init
    • worker_init
    • worker_ready
    • heartbeat_sent
    • worker_shutting_down
    • worker_process_init
    • worker_process_shutdown
    • worker_shutdown
  – Beat Signals
    • beat_init
    • beat_embedded_init
  – Eventlet Signals
    • eventlet_pool_started
    • eventlet_pool_preshutdown
    • eventlet_pool_postshutdown
    • eventlet_pool_apply
  – Logging Signals
Signals allow decoupled applications to receive notifications when certain actions occur elsewhere in the application. Celery ships with many signals that your application can hook into to augment behavior of certain actions.

**Basics**

Several kinds of events trigger signals, you can connect to these signals to perform actions as they trigger.

Example connecting to the `after_task_publish` signal:

```python
from celery.signals import after_task_publish

@after_task_publish.connect
def task_sent_handler(sender=None, headers=None, body=None, **kwargs):
    info = headers if 'task' in headers else body
    print('after_task_publish for task id {info["id"]}'.format(info=info,
                                                               kwargs=kwargs))
```

Some signals also have a sender you can filter by. For example the `after_task_publish` signal uses the task name as a sender, so by providing the `sender` argument to `connect` you can connect your handler to be called every time a task with name “proj.tasks.add” is published:

```python
@after_task_publish.connect(sender='proj.tasks.add')
def task_sent_handler(sender=None, headers=None, body=None, **kwargs):
    info = headers if 'task' in headers else body
    print('after_task_publish for task id {info["id"]}'.format(info=info,
                                                                kwargs=kwargs))
```

Signals use the same implementation as `django.core.dispatch`. As a result other keyword parameters (e.g., `signal`) are passed to all signal handlers by default.

The best practice for signal handlers is to accept arbitrary keyword arguments (i.e., `**kwargs`). That way new Celery versions can add additional arguments without breaking user code.

**Signals**

**Task Signals**
**before_task_publish**

New in version 3.1.

Dispatched before a task is published. Note that this is executed in the process sending the task.

Sender is the name of the task being sent.

Provides arguments:

- **body**
  
  Task message body.
  
  This is a mapping containing the task message fields, see Version 2 and Version 1 for a reference of possible fields that can be defined.

- **exchange**
  
  Name of the exchange to send to or a Exchange object.

- **routing_key**
  
  Routing key to use when sending the message.

- **headers**
  
  Application headers mapping (can be modified).

- **properties**
  
  Message properties (can be modified)

- **declare**
  
  List of entities (Exchange, Queue, or binding) to declare before publishing the message. Can be modified.

- **retry_policy**
  
  Mapping of retry options. Can be any argument to kombu.Connection.ensure() and can be modified.

**after_task_publish**

Dispatched when a task has been sent to the broker. Note that this is executed in the process that sent the task.

Sender is the name of the task being sent.

Provides arguments:

- **headers**
  
  The task message headers, see Version 2 and Version 1 for a reference of possible fields that can be defined.

- **body**
  
  The task message body, see Version 2 and Version 1 for a reference of possible fields that can be defined.

- **exchange**
  
  Name of the exchange or Exchange object used.

- **routing_key**
Routing key used.

**task_prerun**

Dispatched before a task is executed. Sender is the task object being executed.

Provides arguments:

- `task_id`
  - Id of the task to be executed.
- `task`
  - The task being executed.
- `args`
  - The tasks positional arguments.
- `kwargs`
  - The tasks keyword arguments.

**task_postrun**

Dispatched after a task has been executed. Sender is the task object executed.

Provides arguments:

- `task_id`
  - Id of the task to be executed.
- `task`
  - The task being executed.
- `args`
  - The tasks positional arguments.
- `kwargs`
  - The tasks keyword arguments.
- `retval`
  - The return value of the task.
- `state`
  - Name of the resulting state.
**task retry**

Dispatched when a task will be retried.  
Sender is the task object.  
Provides arguments:

- **request**  
  The current task request.

- **reason**  
  Reason for retry (usually an exception instance, but can always be coerced to `str`).

- **einfo**  
  Detailed exception information, including traceback (a `billiard.einfo.ExceptionInfo` object).

**task success**

Dispatched when a task succeeds.  
Sender is the task object executed.  
Provides arguments

- **result**  
  Return value of the task.

**task failure**

Dispatched when a task fails.  
Sender is the task object executed.  
Provides arguments:

- **task_id**  
  Id of the task.

- **exception**  
  Exception instance raised.

- **args**  
  Positional arguments the task was called with.

- **kwargs**  
  Keyword arguments the task was called with.

- **traceback**  
  Stack trace object.

- **einfo**  
  The `billiard.einfo.ExceptionInfo` instance.
**task_received**

Dispatched when a task is received from the broker and is ready for execution.

Sender is the consumer object.

Provides arguments:

- **request**

  This is a `Request` instance, and not `task.request`. When using the prefork pool this signal is dispatched in the parent process, so `task.request` isn’t available and shouldn’t be used. Use this object instead, as they share many of the same fields.

**task_revoked**

Dispatched when a task is revoked/terminated by the worker.

Sender is the task object revoked/terminated.

Provides arguments:

- **request**

  This is a `Request` instance, and not `task.request`. When using the prefork pool this signal is dispatched in the parent process, so `task.request` isn’t available and shouldn’t be used. Use this object instead, as they share many of the same fields.

- **terminated**

  Set to True if the task was terminated.

- **signum**

  Signal number used to terminate the task. If this is None and terminated is True then TERM should be assumed.

- **expired**

  Set to True if the task expired.

**task_unknown**

Dispatched when a worker receives a message for a task that’s not registered.

Sender is the worker `Consumer`.

Provides arguments:

- **name**

  Name of task not found in registry.

- **id**

  The task id found in the message.

- **message**

  Raw message object.

- **exc**

  The error that occurred.
task_rejected

Dispatched when a worker receives an unknown type of message to one of its task queues.

Sender is the worker Consumer.

Provides arguments:

- **message**
  Raw message object.
- **exc**
  The error that occurred (if any).

App Signals

import_modules

This signal is sent when a program (worker, beat, shell) etc, asks for modules in the include and imports settings to be imported.

Sender is the app instance.

Worker Signals

celeryd_after_setup

This signal is sent after the worker instance is set up, but before it calls run. This means that any queues from the celery worker -Q option is enabled, logging has been set up and so on.

It can be used to add custom queues that should always be consumed from, disregarding the celery worker -Q option. Here’s an example that sets up a direct queue for each worker, these queues can then be used to route a task to any specific worker:

```python
from celery.signals import celeryd_after_setup

@celeryd_after_setup.connect
def setup_direct_queue(sender, instance, **kwargs):
    queue_name = '{0}.dq'.format(sender)  # sender is the nodename of the worker
    instance.app.amqp.queues.select_add(queue_name)
```

Provides arguments:

- **sender**
  Node name of the worker.

- **instance**
  This is the celery.apps.worker.Worker instance to be initialized. Note that only the app and hostname (nodename) attributes have been set so far, and the rest of __init__ hasn’t been executed.

- **conf**
  The configuration of the current app.
celeryd_init

This is the first signal sent when celery worker starts up. The sender is the host name of the worker, so this signal can be used to setup worker specific configuration:

```python
from celery.signals import celeryd_init

@celeryd_init.connect(sender='worker12@example.com')
def configure_worker12(conf=None, **kwargs):
    conf.task_default_rate_limit = '10/m'
```

or to set up configuration for multiple workers you can omit specifying a sender when you connect:

```python
from celery.signals import celeryd_init

@celeryd_init.connect
def configure_workers(sender=None, conf=None, **kwargs):
    if sender in ('worker1@example.com', 'worker2@example.com'):
        conf.task_default_rate_limit = '10/m'
    if sender == 'worker3@example.com':
        conf.worker_prefetch_multiplier = 0
```

Provides arguments:

- **sender**
  
  Nodename of the worker.

- **instance**
  
  This is the celery.apps.worker.Worker instance to be initialized. Note that only the app and hostname (nodename) attributes have been set so far, and the rest of __init__ hasn’t been executed.

- **conf**
  
  The configuration of the current app.

- **options**
  
  Options passed to the worker from command-line arguments (including defaults).

worker_init

Dispatched before the worker is started.

worker_ready

Dispatched when the worker is ready to accept work.

heartbeat_sent

Dispatched when Celery sends a worker heartbeat. 

Sender is the celery.worker.heartbeat.Heart instance.
**worker_shutting_down**

Dispatched when the worker begins the shutdown process.

Provides arguments:

- **sig**
  
  The POSIX signal that was received.

- **how**
  
  The shutdown method, warm or cold.

- **exitcode**
  
  The exitcode that will be used when the main process exits.

**worker_process_init**

Dispatched in all pool child processes when they start.

Note that handlers attached to this signal mustn’t be blocking for more than 4 seconds, or the process will be killed assuming it failed to start.

**worker_process_shutdown**

Dispatched in all pool child processes just before they exit.

Note: There’s no guarantee that this signal will be dispatched, similarly to `finally` blocks it’s impossible to guarantee that handlers will be called at shutdown, and if called it may be interrupted during.

Provides arguments:

- **pid**
  
  The pid of the child process that’s about to shutdown.

- **exitcode**
  
  The exitcode that’ll be used when the child process exits.

**worker_shutdown**

Dispatched when the worker is about to shut down.

**Beat Signals**

**beat_init**

Dispatched when `celery beat` starts (either standalone or embedded).

Sender is the `celery.beat.Service` instance.
beat_embedded_init

Dispatched in addition to the beat_init signal when celery beat is started as an embedded process.
Sender is the celery.beat.Service instance.

Eventlet Signals

eventlet_pool_started

Sent when the eventlet pool has been started.
Sender is the celery.concurrency.eventlet.TaskPool instance.

eventlet_pool_preshutdown

Sent when the worker shutdown, just before the eventlet pool is requested to wait for remaining workers.
Sender is the celery.concurrency.eventlet.TaskPool instance.

eventlet_pool_postshutdown

Sent when the pool has been joined and the worker is ready to shutdown.
Sender is the celery.concurrency.eventlet.TaskPool instance.

eventlet_pool_apply

Sent whenever a task is applied to the pool.
Sender is the celery.concurrency.eventlet.TaskPool instance.
Provides arguments:
- target
  The target function.
- args
  Positional arguments.
- kwargs
  Keyword arguments.

Logging Signals

setup_logging

Celery won’t configure the loggers if this signal is connected, so you can use this to completely override the logging configuration with your own.
If you’d like to augment the logging configuration setup by Celery then you can use the after_setup_logger and after_setup_task_logger signals.
Provides arguments:

- loglevel
  The level of the logging object.
- logfile
  The name of the logfile.
- format
  The log format string.
- colorize
  Specify if log messages are colored or not.

**after_setup_logger**

Sent after the setup of every global logger (not task loggers). Used to augment logging configuration.

Provides arguments:

- logger
  The logger object.
- loglevel
  The level of the logging object.
- logfile
  The name of the logfile.
- format
  The log format string.
- colorize
  Specify if log messages are colored or not.

**after_setup_task_logger**

Sent after the setup of every single task logger. Used to augment logging configuration.

Provides arguments:

- logger
  The logger object.
- loglevel
  The level of the logging object.
- logfile
  The name of the logfile.
- format
  The log format string.
• **colorize**
  
  Specify if log messages are colored or not.

## Command signals

### user_preload_options

This signal is sent after any of the Celery command line programs are finished parsing the user preload options.

It can be used to add additional command-line arguments to the `celery` umbrella command:

```python
from celery import Celery
from celery import signals
from celery.bin.base import Option

app = Celery()
app.user_options['preload'].add(Option(
    '--monitoring', action='store_true',
    help='Enable our external monitoring utility, blahblah',
))

@signals.user_preload_options.connect
def handle_preload_options(options, **kwargs):
    if options['monitoring']:
        enable_monitoring()
```

Sender is the `Command` instance, and the value depends on the program that was called (e.g., for the umbrella command it’ll be a `CeleryCommand` object).

Provides arguments:

- **app**
  
  The app instance.

- **options**
  
  Mapping of the parsed user preload options (with default values).

## Deprecated Signals

### task_sent

This signal is deprecated, please use `after_task_publish` instead.

### 3.3.15 Testing with Celery

#### Tasks and unit tests

To test task behavior in unit tests the preferred method is mocking.

**Eager mode**

The eager mode enabled by the `task_always_eager` setting is by definition not suitable for unit tests.
When testing with eager mode you are only testing an emulation of what happens in a worker, and there are many discrepancies between the emulation and what happens in reality.

A Celery task is much like a web view, in that it should only define how to perform the action in the context of being called as a task.

This means optimally tasks only handle things like serialization, message headers, retries, and so on, with the actual logic implemented elsewhere.

Say we had a task like this:

```python
from .models import Product

@app.task(bind=True)
def send_order(self, product_pk, quantity, price):
    price = Decimal(price)  # json serializes this to string.

    # models are passed by id, not serialized.
    product = Product.objects.get(product_pk)

    try:
        product.order(quantity, price)
    except OperationalError as exc:
        raise self.retry(exc=exc)
```

Note: A task being bound means the first argument to the task will always be the task instance (self). which means you do get a self argument as the first argument and can use the Task class methods and attributes.

You could write unit tests for this task, using mocking like in this example:

```python
from pytest import raises
from celery.exceptions import Retry
# for python 2: use mock.patch from `pip install mock`
from unittest.mock import patch
from proj.models import Product
from proj.tasks import send_order

class test_send_order:
    @patch('proj.tasks.Product.order')  # < patching Product in module above
    def test_success(self, product_order):
        product = Product.objects.create(name='Foo',
                                        )
        send_order(product.pk, 3, Decimal(30.3))
        product_order.assert_called_with(3, Decimal(30.3))

    @patch('proj.tasks.Product.order')
    @patch('proj.tasks.send_order.retry')
    def test_failure(self, send_order_retry, product_order):
        product = Product.objects.create(name='Foo',
                                        )
```

(continues on next page)
# Set a side effect on the patched methods
# so that they raise the errors we want.
send_order_retry.side_effect = Retry()
product_order.side_effect = OperationalError()

    with raises(Retry):
        send_order(product.pk, 3, Decimal(30.6))

Pytest

New in version 4.0.

Celery is also a pytest plugin that adds fixtures that you can use in your integration (or unit) test suites.

Marks

celery - Set test app configuration.

The celery mark enables you to override the configuration used for a single test case:

```python
@pytest.mark.celery(result_backend='redis://')
def test_something():
    ...
```

or for all the test cases in a class:

```python
@pytest.mark.celery(result_backend='redis://')
class test_something:
    
        def test_one(self):
            ...

        def test_two(self):
            ...
```

Fixtures

Function scope

celery_app - Celery app used for testing.

This fixture returns a Celery app you can use for testing.

Example:

```python
def test_create_task(celery_app, celery_worker):
    @celery_app.task
    def mul(x, y):
        return x * y

    assert mul.delay(4, 4).get(timeout=10) == 16
```
**celery_worker** - Embed live worker.

This fixture starts a Celery worker instance that you can use for integration tests. The worker will be started in a separate thread and will be shutdown as soon as the test returns.

Example:

```python
# Put this in your conftest.py
@pytest.fixture(scope='session')
def celery_config():
    return {
        'broker_url': 'amqp://',
        'result_backend': 'redis://'
    }

def test_add(celery_worker):
    mytask.delay()

# If you wish to override some setting in one test cases only - you can use the `celery` mark:
@ pytest.mark.celery(result_backend='rpc')
def test_other(celery_worker):
    ...
```

**Session scope**

**celery_config** - Override to setup Celery test app configuration.

You can redefine this fixture to configure the test Celery app.

The config returned by your fixture will then be used to configure the celery_app(), and celery_session_app() fixtures.

Example:

```python
@ pytest.fixture(scope='session')
def celery_config():
    return {
        'broker_url': 'amqp://',
        'result_backend': 'rpc',
    }
```

**celery_parameters** - Override to setup Celery test app parameters.

You can redefine this fixture to change the __init__ parameters of test Celery app. In contrast to celery_config(), these are directly passed to when instantiating Celery.

The config returned by your fixture will then be used to configure the celery_app(), and celery_session_app() fixtures.

Example:
@pytest.fixture(scope='session')
def celery_parameters():
    return {
        'task_cls': my.package.MyCustomTaskClass,
        'strict_typing': False,
    }

celery_worker_parameters - Override to setup Celery worker parameters.

You can redefine this fixture to change the __init__ parameters of test Celery workers. These are directly passed to WorkController when it is instantiated.

The config returned by your fixture will then be used to configure the celery_worker(), and celery_session_worker() fixtures.

Example:

@ pytest.fixture(scope='session')
def celery_worker_parameters():
    return {
        'queues': ('high-prio', 'low-prio'),
        'exclude_queues': ('celery'),
    }

celery_enable_logging - Override to enable logging in embedded workers.

This is a fixture you can override to enable logging in embedded workers.

Example:

@ pytest.fixture(scope='session')
def celery_enable_logging():
    return True

celery_includes - Add additional imports for embedded workers.

You can override fixture to include modules when an embedded worker starts.

You can have this return a list of module names to import, which can be task modules, modules registering signals, and so on.

Example:

@ pytest.fixture(scope='session')
def celery_includes():
    return ['proj.tests.tasks', 'proj.tests.celery_signal_handlers',]
**celery_worker_pool** - **Override the pool used for embedded workers.**

You can override fixture to configure the execution pool used for embedded workers.

Example:

```python
@py.test.fixture(scope='session')
def celery_worker_pool():
    return 'prefork'
```

**Warning:** You cannot use the gevent/eventlet pools, that is unless your whole test suite is running with the monkeypatches enabled.

**celery_session_worker** - **Embedded worker that lives throughout the session.**

This fixture starts a worker that lives throughout the testing session (it won’t be started/stopped for every test).

Example:

```python
# Add this to your conftest.py
@py.test.fixture(scope='session')
def celery_config():
    return {
        'broker_url': 'amqp://',
        'result_backend': 'rpc',
    }

# Do this in your tests.
def test_add_task(celery_session_worker):
    assert add.delay(2, 2) == 4
```

**Warning:** It’s probably a bad idea to mix session and ephemeral workers...

**celery_session_app** - **Celery app used for testing (session scope).**

This can be used by other session scoped fixtures when they need to refer to a Celery app instance.

**use_celery_app_trap** - **Raise exception on falling back to default app.**

This is a fixture you can override in your conftest.py, to enable the “app trap”: if something tries to access the default or current_app, an exception is raised.

Example:

```python
@py.test.fixture(scope='session')
def use_celery_app_trap():
    return True
```

If a test wants to access the default app, you would have to mark it using the depends_on_current_app fixture:
@pytest.mark.usefixtures('depends_on_current_app')
def test_something():
    something()

### 3.3.16 Extensions and Bootsteps

- **Custom Message Consumers**
- **Blueprints**
- **Worker**
  - Attributes
  - Example worker bootstep
- **Consumer**
  - Attributes
  - Methods
- **Installing Bootsteps**
- **Command-line programs**
  - Adding new command-line options
  - Adding new celery sub-commands
- **Worker API**
  - **Hub** - The workers async event loop
  - **Timer** - Scheduling events

#### Custom Message Consumers

You may want to embed custom Kombu consumers to manually process your messages.

For that purpose a special `ConsumerStep` bootstep class exists, where you only need to define the `get_consumers` method, that must return a list of `kombu.Consumer` objects to start whenever the connection is established:

```python
from celery import Celery
from celery import bootsteps
from kombu import Consumer, Exchange, Queue

my_queue = Queue('custom', Exchange('custom'), 'routing_key')

app = Celery(broker='amqp://')

class MyConsumerStep(bootsteps.ConsumerStep):
    def get_consumers(self, channel):
        return [Consumer(channel,}
queues=[my_queue],
callbacks=[self.handle_message],
accept=['json'])]

    def handle_message(self, body, message):
        print('Received message: {0!r}'.format(body))
        message.ack()
app.steps['consumer'].add(MyConsumerStep)

def send_me_a_message(who, producer=None):
    with app.producer_or_acquire(producer) as producer:
        producer.publish(
            {'hello': who},
            exchange=my_queue.exchange,
            routing_key='routing_key',
            declare=[my_queue],
            retry=True,
        )

if __name__ == '__main__':
    send_me_a_message('world!')

Note: Kombu Consumers can take use of two different message callback dispatching mechanisms. The first one is the callbacks argument that accepts a list of callbacks with a (body, message) signature, the second one is the on_message argument that takes a single callback with a (message,) signature. The latter won’t automatically decode and deserialize the payload.

    def get_consumers(self, channel):
        return [Consumer(channel, queues=[my_queue],
                         on_message=self.on_message)]

    def on_message(self, message):
        payload = message.decode()
        print('Received message: {0!r} {props!r} rawlen={s}'.format(
            payload, props=message.properties, s=len(message.body),
        ))
        message.ack()

Blueprints

Blueprints is a technique to add functionality to the workers. A bootstep is a custom class that defines hooks to do custom actions at different stages in the worker. Every bootstep belongs to a blueprint, and the worker currently defines two blueprints: **Worker**, and **Consumer**

Figure A: Bootsteps in the Worker and Consumer blueprints. Starting from the bottom up the first step in the worker blueprint is the Timer, and the last step is to start the Consumer blueprint, that then establishes the broker connection and starts consuming messages.
Worker

The Worker is the first blueprint to start, and with it starts major components like the event loop, processing pool, and the timer used for ETA tasks and other timed events.

When the worker is fully started it continues with the Consumer blueprint, that sets up how tasks are executed, connects to the broker and starts the message consumers.

The WorkController is the core worker implementation, and contains several methods and attributes that you can use in your bootstep.

Attributes

app

The current app instance.

hostname

The workers node name (e.g., worker1@example.com)

blueprint

This is the worker Blueprint.

hub

Event loop object (Hub). You can use this to register callbacks in the event loop.

This is only supported by async I/O enabled transports (amqp, redis), in which case the worker.use_eventloop attribute should be set.

Your worker bootstep must require the Hub bootstep to use this:

```python
class WorkerStep(bootsteps.StartStopStep):
    requires = {'celery.worker.components:Hub'}
```

pool

Your worker bootstep must require the Pool bootstep to use this:

```python
class WorkerStep(bootsteps.StartStopStep):
    requires = {'celery.worker.components:Pool'}
```

timer

Timer used to schedule functions.

Your worker bootstep must require the Timer bootstep to use this:

```python
class WorkerStep(bootsteps.StartStopStep):
    requires = {'celery.worker.components:Timer'}
```

statedb

Database <celery.worker.state.Persistent>` to persist state between worker restarts.

This is only defined if the statedb argument is enabled.

Your worker bootstep must require the Statedb bootstep to use this:

```python
class WorkerStep(bootsteps.StartStopStep):
    requires = {'celery.worker.components:Statedb'}
```
**autoscaler**

Autoscaler used to automatically grow and shrink the number of processes in the pool.

This is only defined if the `autoscale` argument is enabled.

Your worker bootstep must require the `Autoscaler` bootstep to use this:

```python
class WorkerStep(bootsteps.StartStopStep):
    requires = ('celery.worker.autoscaler:Autoscaler',)
```

**autoreloader**

Autoreloader used to automatically reload use code when the file-system changes.

This is only defined if the `autoreload` argument is enabled. Your worker bootstep must require the `Autoreloader` bootstep to use this:

```python
class WorkerStep(bootsteps.StartStopStep):
    requires = ('celery.worker.autoreloader:Autoreloader',)
```

### Example worker bootstep

An example Worker bootstep could be:

```python
from celery import bootsteps

class ExampleWorkerStep(bootsteps.StartStopStep):
    requires = ('celery.worker.components:Pool')

    def __init__(self, worker, **kwargs):
        print('Called when the WorkController instance is constructed')
        print('Arguments to WorkController: {0!r}'.format(kwargs))

    def create(self, worker):
        # this method can be used to delegate the action methods
        # to another object that implements "start" and "stop".
        return self

    def start(self, worker):
        print('Called when the worker is started.')

    def stop(self, worker):
        print('Called when the worker shuts down.')

    def terminate(self, worker):
        print('Called when the worker terminates')
```

Every method is passed the current WorkController instance as the first argument.

Another example could use the timer to wake up at regular intervals:

```python
from celery import bootsteps

class DeadlockDetection(bootsteps.StartStopStep):
    requires = ('celery.worker.components:Timer')

    def __init__(self, worker, deadlock_timeout=3600):
```

(continues on next page)
self.timeout = deadlock_timeout
self.requests = []
self.tref = None

def start(self, worker):
    # run every 30 seconds.
    self.tref = worker.timer.call_repeatedly(30.0, self.detect, (worker,), priority=10,
)

def stop(self, worker):
    if self.tref:
        self.tref.cancel()
        self.tref = None

def detect(self, worker):
    # update active requests
    for req in worker.active_requests:
        if req.time_start and time() - req.time_start > self.timeout:
            raise SystemExit()

Consumer

The Consumer blueprint establishes a connection to the broker, and is restarted every time this connection is lost. Consumer bootsteps include the worker heartbeat, the remote control command consumer, and importantly, the task consumer.

When you create consumer bootsteps you must take into account that it must be possible to restart your blueprint. An additional ‘shutdown’ method is defined for consumer bootsteps, this method is called when the worker is shutdown.

Attributes

app
    The current app instance.

controller
    The parent WorkController object that created this consumer.

hostname
    The workers node name (e.g., worker1@example.com)

blueprint
    This is the worker Blueprint.

hub
    Event loop object (Hub). You can use this to register callbacks in the event loop.

    This is only supported by async I/O enabled transports (amqp, redis), in which case the worker.use_eventloop
    attribute should be set.

    Your worker bootstep must require the Hub bootstep to use this:

class WorkerStep(bootsteps.StartStopStep):
    requires = {'celery.worker.components:Hub'}
The current broker connection (`kombu.Connection`).

A consumer bootstep must require the ‘Connection’ bootstep to use this:

```python
class Step(bootsteps.StartStopStep):
    requires = {'celery.worker.consumer.connection:Connection'}
```

event_dispatcher

A `app.events.Dispatcher` object that can be used to send events.

A consumer bootstep must require the `Events` bootstep to use this.

```python
class Step(bootsteps.StartStopStep):
    requires = {'celery.worker.consumer.events:Events'}
```

gossip

Worker to worker broadcast communication (`Gossip`).

A consumer bootstep must require the `Gossip` bootstep to use this.

```python
class RatelimitStep(bootsteps.StartStopStep):
    '''Rate limit tasks based on the number of workers in the cluster.'''
    requires = {'celery.worker.consumer.gossip:Gossip'}

    def start(self, c):
        self.c = c
        self.c.gossip.on.node_join.add(self.on_cluster_size_change)
        self.c.gossip.on.node_leave.add(self.on_cluster_size_change)
        self.c.gossip.on.node_lost.add(self.on_node_lost)
        self.tasks = [
            self.app.tasks['proj.tasks.add'],
            self.app.tasks['proj.tasks.mul']
        ]
        self.last_size = None

    def on_cluster_size_change(self, worker):
        cluster_size = len(list(self.c.gossip.state.alive_workers()))
        if cluster_size != self.last_size:
            for task in self.tasks:
                task.rate_limit = 1.0 / cluster_size
            self.c.reset_rate_limits()
            self.last_size = cluster_size

    def on_node_lost(self, worker):
        # may have processed heartbeat too late, so wake up soon
        # in order to see if the worker recovered.
        self.c.timer.call_after(10.0, self.on_cluster_size_change)
```

Callbacks

- `<set> gossip.on.node_join`
  Called whenever a new node joins the cluster, providing a `Worker` instance.

- `<set> gossip.on.node_leave`
  Called whenever a new node leaves the cluster (shuts down), providing a `Worker` instance.

- `<set> gossip.on.node_lost`
Called whenever heartbeat was missed for a worker instance in the cluster (heartbeat not received or processed in time), providing a Worker instance.

This doesn’t necessarily mean the worker is actually offline, so use a time out mechanism if the default heartbeat timeout isn’t sufficient.

**pool**

**timer**

Timer `<celery.utils.timer2.Schedule` used to schedule functions.

**heart**

Responsible for sending worker event heartbeats (`Heart`).

Your consumer bootstep must require the `Heart` bootstep to use this:

```python
class Step(bootsteps.StartStopStep):
    requires = {'celery.worker.consumer.heart:Heart'}
```

**task_consumer**

The `kombu.Consumer` object used to consume task messages.

Your consumer bootstep must require the `Tasks` bootstep to use this:

```python
class Step(bootsteps.StartStopStep):
    requires = {'celery.worker.consumer.tasks:Tasks'}
```

**strategies**

Every registered task type has an entry in this mapping, where the value is used to execute an incoming message of this task type (the task execution strategy). This mapping is generated by the `Tasks` bootstep when the consumer starts:

```python
for name, task in app.tasks.items():
    strategies[name] = task.start_strategy(app, consumer)
    task.__trace__ = celery.app.trace.build_tracer(
        name, task, loader, hostname
    )
```

Your consumer bootstep must require the `Tasks` bootstep to use this:

```python
class Step(bootsteps.StartStopStep):
    requires = {'celery.worker.consumer.tasks:Tasks'}
```

**task_buckets**

A `defaultdict` used to look-up the rate limit for a task by type. Entries in this dict may be None (for no limit) or a `TokenBucket` instance implementing `consume(tokens)` and `expected_time(tokens)`.

TokenBucket implements the token bucket algorithm, but any algorithm may be used as long as it conforms to the same interface and defines the two methods above.

**qos**

The QoS object can be used to change the task channels current prefetch_count value:

```python
# increment at next cycle
consumer.qos.increment_eventually(1)
# decrement at next cycle
consumer.qos.decrement_eventually(1)
consumer.qos.set(10)
```
Methods

```python
consumer.reset_rate_limits()

Updates the task_buckets mapping for all registered task types.

consumer.bucket_for_task(type, Bucket=TokenBucket)

Creates rate limit bucket for a task using its task.rate_limit attribute.

consumer.add_task_queue(name, exchange=None, exchange_type=None, routing_key=None, **options):

Adds new queue to consume from. This will persist on connection restart.

consumer.cancel_task_queue(name)

Stop consuming from queue by name. This will persist on connection restart.

apply_eta_task(request)

Schedule ETA task to execute based on the request.eta attribute. (Request)
```

Installing Bootsteps

app.steps['worker'] and app.steps['consumer'] can be modified to add new bootsteps:

```python
>>> app = Celery()
>>> app.steps['worker'].add(MyWorkerStep)  # < add class, don't instantiate
>>> app.steps['consumer'].add(MyConsumerStep)

>>> app.steps['consumer'].update([StepA, StepB])

>>> app.steps['consumer'][
]
```

The order of steps isn’t important here as the order is decided by the resulting dependency graph (Step.requires).

To illustrate how you can install bootsteps and how they work, this is an example step that prints some useless debug-
ging information. It can be added both as a worker and consumer bootstep:

```python
from celery import Celery
from celery import bootsteps

class InfoStep(bootsteps.Step):
    def __init__(self, parent, **kwargs):
        # here we can prepare the Worker/Consumer object
        # in any way we want, set attribute defaults, and so on.
        print('{} is in init'.format(parent))

    def start(self, parent):
        # our step is started together with all other Worker/Consumer
        # bootsteps.
        print('{} is starting'.format(parent))

    def stop(self, parent):
        # the Consumer calls stop every time the consumer is
        # restarted (i.e., connection is lost) and also at shutdown.
        # The Worker will call stop at shutdown only.
        print('{} is stopping'.format(parent))
```

(continues on next page)
def shutdown(self, parent):
    # shutdown is called by the Consumer at shutdown, it's not
    # called by Worker.
    print('{0!r} is shutting down'.format(parent))

app = Celery(broker='amqp://')
app.steps['worker'].add(InfoStep)
app.steps['consumer'].add(InfoStep)

Starting the worker with this step installed will give us the following logs:

The print statements will be redirected to the logging subsystem after the worker has been initialized, so the “is starting” lines are time-stamped. You may notice that this does no longer happen at shutdown, this is because the stop and shutdown methods are called inside a signal handler, and it’s not safe to use logging inside such a handler. Logging with the Python logging module isn’t reentrant: meaning you cannot interrupt the function then call it again later. It’s important that the stop and shutdown methods you write is also reentrant.

Starting the worker with --loglevel=debug will show us more information about the boot process:
Command-line programs

Adding new command-line options

Command-specific options

You can add additional command-line options to the worker, beat, and events commands by modifying the user_options attribute of the application instance.

Celery commands use the argparse module to parse command-line arguments, and so to add custom arguments you need to specify a callback that takes an argparse.ArgumentParser instance - and adds arguments. Please see the argparse documentation to read about the fields supported.

Example adding a custom option to the celery worker command:

```python
from celery import Celery

app = Celery(broker='amqp://')

def add_worker_arguments(parser):
    parser.add_argument('--enable-my-option', action='store_true', default=False,
                        help='Enable custom option.',
                        ),
    app.user_options['worker'].add(add_worker_arguments)

All bootsteps will now receive this argument as a keyword argument to Bootstep.__init__:

```python
from celery import bootsteps

class MyBootstep(bootsteps.Step):
    def __init__(self, parent, enable_my_option=False, **options):
        super().__init__(parent, **options)
        if enable_my_option:
            party()

app.steps['worker'].add(MyBootstep)
```
Preload options

The celery umbrella command supports the concept of ‘preload options’. These are special options passed to all sub-commands and parsed outside of the main parsing step.

The list of default preload options can be found in the API reference: celery.bin.base.

You can add new preload options too, for example to specify a configuration template:

```python
from celery import Celery
from celery import signals
from celery.bin import Option

app = Celery()

def add_preload_options(parser):
    parser.add_argument(  
        '-Z', '--template', default='default',  
        help='Configuration template to use.',
    )

app.user_options['preload'].add(add_preload_options)

@signals.user_preload_options.connect

def on_preload_parsed(options, **kwargs):
    use_template(options['template'])
```

Adding new celery sub-commands

New commands can be added to the celery umbrella command by using setuptools entry-points.

Entry-points is special meta-data that can be added to your packages setup.py program, and then after installation, read from the system using the pkg_resources module.

Celery recognizes celery.commands entry-points to install additional sub-commands, where the value of the entry-point must point to a valid subclass of celery.bin.base.Command. There’s limited documentation, unfortunately, but you can find inspiration from the various commands in the celery.bin package.

This is how the Flower monitoring extension adds the celery flower command, by adding an entry-point in setup.py:

```python
setup(
    name='flower',
    entry_points={
        'celery.commands': [
            'flower = flower.command:FlowerCommand',
        ],
    },
)
```

The command definition is in two parts separated by the equal sign, where the first part is the name of the sub-command (flower), then the second part is the fully qualified symbol path to the class that implements the command:

```
flower.command:FlowerCommand
```

The module path and the name of the attribute should be separated by colon as above.

In the module flower/command.py, the command class is defined something like this:
```python
from celery.bin.base import Command

class FlowerCommand(Command):
    def add_arguments(self, parser):
        parser.add_argument('--port', default=8888, type=int,
                            help='Webserver port',
                        )
        parser.add_argument('--debug', action='store_true',
                        )

    def run(self, port=None, debug=False, **kwargs):
        print('Running our command')
```

Worker API

**Hub - The workers async event loop**

*supported transports*  amqp, redis

New in version 3.0.

The worker uses asynchronous I/O when the amqp or redis broker transports are used. The eventual goal is for all transports to use the event-loop, but that will take some time so other transports still use a threading-based solution.

- `hub.add(fd, callback, flags)`
- `hub.add_reader(fd, callback, *args)`
  Add callback to be called when `fd` is readable.
  
  The callback will stay registered until explicitly removed using `hub.remove(fd)`, or the file descriptor is automatically discarded because it’s no longer valid.
  
  Note that only one callback can be registered for any given file descriptor at a time, so calling `add` a second time will remove any callback that was previously registered for that file descriptor.

  A file descriptor is any file-like object that supports the `fileno` method, or it can be the file descriptor number (int).

- `hub.add_writer(fd, callback, *args)`
  Add callback to be called when `fd` is writable. See also notes for `hub.add_reader()` above.

- `hub.remove(fd)`
  Remove all callbacks for file descriptor `fd` from the loop.

**Timer - Scheduling events**

- `timer.call_after(secs, callback, args=(), kwargs=(), priority=0)`
- `timer.call_repeatedly(secs, callback, args=(), kwargs=(), priority=0)`
- `timer.call_at(eta, callback, args=(), kwargs=(), priority=0)`
3.3.17 Configuration and defaults

This document describes the configuration options available.

If you’re using the default loader, you must create the `celeryconfig.py` module and make sure it’s available on the Python path.

- Example configuration file
- New lowercase settings
- Configuration Directives
  - General settings
  - Time and date settings
  - Task settings
  - Task execution settings
  - Task result backend settings
  - Database backend settings
  - RPC backend settings
  - Cache backend settings
  - Redis backend settings
  - Cassandra backend settings
  - S3 backend settings
  - Azure Block Blob backend settings
  - Elasticsearch backend settings
  - Riak backend settings
  - AWS DynamoDB backend settings
  - IronCache backend settings
  - Couchbase backend settings
  - ArangoDB backend settings
  - CosmosDB backend settings (experimental)
  - CouchDB backend settings
  - File-system backend settings
  - Consul K/V store backend settings
  - Message Routing
  - Broker Settings
  - Worker
  - Events
  - Remote Control Commands
  - Logging
Example configuration file

This is an example configuration file to get you started. It should contain all you need to run a basic Celery set-up.

```python
## Broker settings.
broker_url = 'amqp://guest:guest@localhost:5672//'

# List of modules to import when the Celery worker starts.
imports = ('myapp.tasks',)

## Using the database to store task state and results.
result_backend = 'db+sqlite:///results.db'

# Newcase settings

task_annotations = {'tasks.add': {'rate_limit': '10/s'}}
```

New lowercase settings

Version 4.0 introduced new lower case settings and setting organization.

The major difference between previous versions, apart from the lower case names, are the renaming of some prefixes, like `celery_beat_` to `beat_`, `celeryd_` to `worker_`, and most of the top level `celery_` settings have been moved into a new `task_` prefix.

**Note:** Celery will still be able to read old configuration files, so there’s no rush in moving to the new settings format. Furthermore, we provide the `celery upgrade` command that should handle plenty of cases (including Django).

Configuration Directives

General settings

**accept_content**

Default: `{ 'json' }` (set, list, or tuple).

A white-list of content-types/serializers to allow.

If a message is received that’s not in this list then the message will be discarded with an error.

By default only json is enabled but any content type can be added, including pickle and yaml; when this is the case make sure untrusted parties don’t have access to your broker. See Security for more.

Example:

```python
# using serializer name
accept_content = ['json']
```
result_accept_content

Default: None (can be set, list or tuple).

New in version 4.3.

A white-list of content-types/serializers to allow for the result backend.

If a message is received that’s not in this list then the message will be discarded with an error.

By default it is the same serializer as accept_content. However, a different serializer for accepted content of the result backend can be specified. Usually this is needed if signed messaging is used and the result is stored unsigned in the result backend. See Security for more.

Example:

```python
# using serializer name
result_accept_content = ['json']

# or the actual content-type (MIME)
result_accept_content = ['application/json']
```

Time and date settings

enable_utc

New in version 2.5.

Default: Enabled by default since version 3.0.

If enabled dates and times in messages will be converted to use the UTC timezone.

Note that workers running Celery versions below 2.5 will assume a local timezone for all messages, so only enable if all workers have been upgraded.

timezone

New in version 2.5.

Default: "UTC".

Configure Celery to use a custom time zone. The timezone value can be any time zone supported by the pytz library.

If not set the UTC timezone is used. For backwards compatibility there’s also a enable_utc setting, and when this is set to false the system local timezone is used instead.

Task settings
task_annotations

New in version 2.5.
Default: None.
This setting can be used to rewrite any task attribute from the configuration. The setting can be a dict, or a list of annotation objects that filter for tasks and return a map of attributes to change.
This will change the rate_limit attribute for the tasks.add task:

```python
task_annotations = {'tasks.add': {'rate_limit': '10/s'}}
```

or change the same for all tasks:

```python
task_annotations = {'*': {'rate_limit': '10/s'}}
```

You can change methods too, for example the on_failure handler:

```python
def my_on_failure(self, exc, task_id, args, kwargs, einfo):
    print('Oh no! Task failed: {0!r}'.format(exc))

task_annotations = {'*': {'on_failure': my_on_failure}}
```

If you need more flexibility then you can use objects instead of a dict to choose the tasks to annotate:

```python
class MyAnnotate(object):
    def annotate(self, task):
        if task.name.startswith('tasks. '):
            return {'rate_limit': '10/s'}

    task_annotations = (MyAnnotate(), {other,})
```

task_compression

Default: None
Default compression used for task messages. Can be gzip, bzip2 (if available), or any custom compression schemes registered in the Kombu compression registry.
The default is to send uncompressed messages.

task_protocol

Default: 2 (since 4.0).
Set the default task message protocol version used to send tasks. Supports protocols: 1 and 2.
Protocol 2 is supported by 3.1.24 and 4.x+.

task_serializer

Default: "json" (since 4.0, earlier: pickle).
A string identifying the default serialization method to use. Can be `json` (default), `pickle`, `yaml`, `msgpack`, or any custom serialization methods that have been registered with `kombu.serialization.registry`.

**See also:**

Serializers.

**task_publish_retry**

New in version 2.2.

Default: Enabled.

Decides if publishing task messages will be retried in the case of connection loss or other connection errors. See also `task_publish_retry_policy`.

**task_publish_retry_policy**

New in version 2.2.

Default: See Message Sending Retry.

Defines the default policy when retrying publishing a task message in the case of connection loss or other connection errors.

**Task execution settings**

**task_always_eager**

Default: Disabled.

If this is `True`, all tasks will be executed locally by blocking until the task returns. `apply_async()` and Task. `delay()` will return an `EagerResult` instance, that emulates the API and behavior of `AsyncResult`, except the result is already evaluated.

That is, tasks will be executed locally instead of being sent to the queue.

**task_eager_propagates**

Default: Disabled.

If this is `True`, eagerly executed tasks (applied by `task.apply()`, or when the `task_always_eager` setting is enabled), will propagate exceptions.

It’s the same as always running `apply()` with `throw=True`.

**task_remote_tracebacks**

Default: Disabled.

If enabled task results will include the workers stack when re-raising task errors.

This requires the `tblib` library, that can be installed using `pip`:
See Bundles for information on combining multiple extension requirements.

**task_ignore_result**

Default: Disabled.

Whether to store the task return values or not (tombstones). If you still want to store errors, just not successful return values, you can set `task_store_errors_even_if_ignored`.

**task_store_errors_even_if_ignored**

Default: Disabled.

If set, the worker stores all task errors in the result store even if `Task.ignore_result` is on.

**task_track_started**

Default: Disabled.

If True the task will report its status as ‘started’ when the task is executed by a worker. The default value is False as the normal behavior is to not report that level of granularity. Tasks are either pending, finished, or waiting to be retried. Having a ‘started’ state can be useful for when there are long running tasks and there’s a need to report what task is currently running.

**task_time_limit**

Default: No time limit.

Task hard time limit in seconds. The worker processing the task will be killed and replaced with a new one when this is exceeded.

**task_soft_time_limit**

Default: No soft time limit.

Task soft time limit in seconds.

The `SoftTimeLimitExceeded` exception will be raised when this is exceeded. For example, the task can catch this to clean up before the hard time limit comes:

```python
from celery.exceptions import SoftTimeLimitExceeded

@app.task
def mytask():
    try:
        return do_work()
    except SoftTimeLimitExceeded:
        cleanup_in_a_hurry()
```
**task_acks_late**

Default: Disabled.

Late ack means the task messages will be acknowledged after the task has been executed, not just before (the default behavior).

**See also:**

FAQ: *Should I use retry or acks_late?*

**task_acks_on_failure_or_timeout**

Default: Enabled

When enabled messages for all tasks will be acknowledged even if they fail or time out.

Configuring this setting only applies to tasks that are acknowledged after they have been executed and only if `task_acks_late` is enabled.

**taskReject_on_worker_lost**

Default: Disabled.

Even if `task_acks_late` is enabled, the worker will acknowledge tasks when the worker process executing them abruptly exits or is signaled (e.g., KILL/INT, etc).

Setting this to true allows the message to be re-queued instead, so that the task will execute again by the same worker, or another worker.

**Warning:** Enabling this can cause message loops; make sure you know what you’re doing.

**task_default_rate_limit**

Default: No rate limit.

The global default rate limit for tasks.

This value is used for tasks that doesn’t have a custom rate limit

**See also:**

The setting: `worker_disable_rate_limits` setting can disable all rate limits.

**Task result backend settings**

**result_backend**

Default: No result backend enabled by default.

The backend used to store task results (tombstones). Can be one of the following:

- rpc Send results back as AMQP messages See [RPC backend settings](#).
• **database** Use a relational database supported by SQLAlchemy. See *Database backend settings*.

• **redis** Use Redis to store the results. See *Redis backend settings*.

• **cache** Use Memcached to store the results. See *Cache backend settings*.

• **cassandra** Use Cassandra to store the results. See *Cassandra backend settings*.

• **elasticsearch** Use Elasticsearch to store the results. See *Elasticsearch backend settings*.

• **ironcache** Use IronCache to store the results. See *IronCache backend settings*.

• **couchbase** Use Couchbase to store the results. See *Couchbase backend settings*.

• **arangodb** Use ArangoDB to store the results. See *ArangoDB backend settings*.

• **couchdb** Use CouchDB to store the results. See *CouchDB backend settings*.

• **cosmosdbsql (experimental)** Use the CosmosDB PaaS to store the results. See *CosmosDB backend settings (experimental)*.

• **filesystem** Use a shared directory to store the results. See *File-system backend settings*.

• **consul** Use the Consul K/V store to store the results. See *Consul K/V store backend settings*.

• **azureblockblob** Use the AzureBlockBlob PaaS store to store the results. See *Azure Block Blob backend settings*.

• **s3** Use the S3 to store the results. See *S3 backend settings*.

### **result_backend_transport_options**

Default: `{}` (empty mapping).

A dict of additional options passed to the underlying transport.

See your transport user manual for supported options (if any).

Example setting the visibility timeout (supported by Redis and SQS transports):

```python
result_backend_transport_options = {'visibility_timeout': 18000}  # 5 hours
```

### **result_serializer**

Default: `json` since 4.0 (earlier: pickle).

Result serialization format.

See *Serializers* for information about supported serialization formats.

### **result_compression**

Default: No compression.

Optional compression method used for task results. Supports the same options as the *task_serializer* setting.
result_extended

Default: False

Enables extended task result attributes (name, args, kwargs, worker, retries, queue, delivery_info) to be written to backend.

result_expires

Default: Expire after 1 day.

Time (in seconds, or a timedelta object) for when after stored task tombstones will be deleted.
A built-in periodic task will delete the results after this time (celery.backend_cleanup), assuming that celery beat is enabled. The task runs daily at 4am.
A value of None or 0 means results will never expire (depending on backend specifications).

Note: For the moment this only works with the AMQP, database, cache, Couchbase, and Redis backends.
When using the database backend, celery beat must be running for the results to be expired.

result_cache_max

Default: Disabled by default.

Enables client caching of results.
This can be useful for the old deprecated ‘amqp’ backend where the result is unavailable as soon as one result instance consumes it.
This is the total number of results to cache before older results are evicted. A value of 0 or None means no limit, and a value of -1 will disable the cache.
Disabled by default.

result_chord_join_timeout

Default: 3.0.

The timeout in seconds (int/float) when joining a group’s results within a chord.

Database backend settings

Database URL Examples

To use the database backend you have to configure the result_backend setting with a connection URL and the db+ prefix:

```
result_backend = 'db+scheme://user:password@host:port/dbname'
```

Examples:
certificate Documentation, Release 4.4.0

# sqlite (filename)
result_backend = 'db+sqlite:///results.sqlite'

# mysql
result_backend = 'db+mysql://scott:tiger@localhost/foo'

# postgresql
result_backend = 'db+postgresql://scott:tiger@localhost/mydatabase'

# oracle
result_backend = 'db+oracle://scott:tiger@127.0.0.1:1521/sidname'

Please see Supported Databases for a table of supported databases, and Connection String for more information about connection strings (this is the part of the URI that comes after the db+ prefix).

database_engine_options

Default: {} (empty mapping).

To specify additional SQLAlchemy database engine options you can use the sqlalchmey_engine_options setting:

```python
# echo enables verbose logging from SQLAlchemy.
app.conf.database_engine_options = {'echo': True}
```

database_short_lived_sessions

Default: Disabled by default.

Short lived sessions are disabled by default. If enabled they can drastically reduce performance, especially on systems processing lots of tasks. This option is useful on low-traffic workers that experience errors as a result of cached database connections going stale through inactivity. For example, intermittent errors like (OperationalError) (2006, ‘MySQL server has gone away’) can be fixed by enabling short lived sessions. This option only affects the database backend.

database_table_names

Default: {} (empty mapping).

When SQLAlchemy is configured as the result backend, Celery automatically creates two tables to store result metadata for tasks. This setting allows you to customize the table names:

```python
# use custom table names for the database result backend.
database_table_names = {
    'task': 'myapp_taskmeta',
    'group': 'myapp_groupmeta',
}
```
RPC backend settings

**result_persistent**

Default: Disabled by default (transient messages).
If set to True, result messages will be persistent. This means the messages won’t be lost after a broker restart.

Example configuration

```python
result_backend = 'rpc://'
result_persistent = False
```

Please note: using this backend could trigger the raise of celery.backends.rpc.BacklogLimitExceeded if the task tombstone is too old.

E.g.

```python
for i in range(10000):
    r = debug_task.delay()
print(r.state) # this would raise celery.backends.rpc.BacklogLimitExceeded
```

Cache backend settings

Note: The cache backend supports the pylibmc and python-memcached libraries. The latter is used only if pylibmc isn’t installed.

Using a single Memcached server:

```python
result_backend = 'cache+memcached://127.0.0.1:11211/
```

Using multiple Memcached servers:

```python
result_backend = """
"""
.strip()
```

The “memory” backend stores the cache in memory only:

```python
result_backend = 'cache'
cache_backend = 'memory'
```

**cache_backend_options**

Default: {} (empty mapping).
You can set pylibmc options using the cache_backend_options setting:
cache_backend_options = {
    'binary': True,
    'behaviors': {'tcp_nodelay': True},
}

cache_backend

This setting is no longer used as it's now possible to specify the cache backend directly in the `result_backend` setting.

Redis backend settings

Configuring the backend URL

**Note:** The Redis backend requires the `redis` library.
To install this package use `pip`:

```
$ pip install celery[redis]
```

See Bundles for information on combining multiple extension requirements.

This backend requires the `result_backend` setting to be set to a Redis or Redis over TLS URL:

```
result_backend = 'redis://:password@host:port/db'
```

For example:

```
result_backend = 'redis://localhost/0'
```

is the same as:

```
result_backend = 'redis://'
```

Use the `rediss://` protocol to connect to redis over TLS:

```
result_backend = 'rediss://:password@host:port/db?ssl_cert_reqs=required'
```

Note that the `ssl_cert_reqs` string should be one of required, optional, or none (though, for backwards compatibility, the string may also be one of CERT_REQUIRED, CERT_OPTIONAL, CERT_NONE).

If a Unix socket connection should be used, the URL needs to be in the format:

```
result_backend = 'socket:///path/to/redis.sock'
```

The fields of the URL are defined as follows:

1. **password**
   
   Password used to connect to the database.

2. **host**
   
   Host name or IP address of the Redis server (e.g., `localhost`).
3. port

Port to the Redis server. Default is 6379.

4. db

Database number to use. Default is 0. The db can include an optional leading slash.

When using a TLS connection (protocol is `rediss://`), you may pass in all values in `broker_use_ssl` as query parameters. Paths to certificates must be URL encoded, and `ssl_cert_reqs` is required. Example:

```python
result_backend = 'rediss://:password@host:port/db?'
    ssl_cert_reqs=required,
    &ssl_ca_certs=/var/ssl/myca.pem  # /var/ssl/myca.pem
    &ssl_certfile=/var/ssl/redis-server-cert.pem  # /var/ssl/redis-server-cert.pem
    &ssl_keyfile=/var/ssl/private/worker-key.pem  # /var/ssl/private/worker-key.pem
```

Note that the `ssl_cert_reqs` string should be one of `required`, `optional`, or `none` (though, for backwards compatibility, the string may also be one of `CERT_REQUIRED`, `CERT_OPTIONAL`, `CERT_NONE`).

**redis_backend_use_ssl**

Default: Disabled.

The Redis backend supports SSL. This value must be set in the form of a dictionary. The valid key-value pairs are the same as the ones mentioned in the `redis` sub-section under `broker_use_ssl`.

**redis_max_connections**

Default: No limit.

Maximum number of connections available in the Redis connection pool used for sending and retrieving results.

**Warning:** Redis will raise a `ConnectionError` if the number of concurrent connections exceeds the maximum.

**redis_socket_connect_timeout**

New in version 4.0.1.

Default: None

Socket timeout for connections to Redis from the result backend in seconds (int/float)

**redis_socket_timeout**

Default: 120.0 seconds.

Socket timeout for reading/writing operations to the Redis server in seconds (int/float), used by the redis result backend.
Cassandra backend settings

**Note:** This Cassandra backend driver requires **cassandra-driver.**
To install, use **pip:**

```
$ pip install celery[cassandra]
```

See **Bundles** for information on combining multiple extension requirements.

This backend requires the following configuration directives to be set.

**cassandra_servers**

Default: `[]` (empty list).
List of host Cassandra servers. For example:

```
cassandra_servers = ['localhost']
```

**cassandra_port**

Default: 9042.
Port to contact the Cassandra servers on.

**cassandra_keyspace**

Default: None.
The key-space in which to store the results. For example:

```
cassandra_keyspace = 'tasks_keyspace'
```

**cassandra_table**

Default: None.
The table (column family) in which to store the results. For example:

```
cassandra_table = 'tasks'
```

**cassandra_read_consistency**

Default: None.
The read consistency used. Values can be **ONE**, **TWO**, **THREE**, **QUORUM**, **ALL**, **LOCAL_QUORUM**, **EACH_QUORUM**, **LOCAL_ONE**.
**cassandra_write_consistency**

Default: None.

The write consistency used. Values can be **ONE**, **TWO**, **THREE**, **QUORUM**, **ALL**, **LOCAL_QUORUM**, **EACH_QUORUM**, **LOCAL_ONE**.

**cassandra_entry_ttl**

Default: None.

Time-to-live for status entries. They will expire and be removed after that many seconds after adding. A value of None (default) means they will never expire.

**cassandra_auth_provider**

Default: None.

AuthProvider class within `cassandra.auth` module to use. Values can be `PlainTextAuthProvider` or `SaslAuthProvider`.

**cassandra_auth_kwargs**

Default: `{}` (empty mapping).

Named arguments to pass into the authentication provider. For example:

```python
    cassandra_auth_kwargs = {
        'username': 'cassandra',
        'password': 'cassandra'
    }
```

**cassandra_options**

Default: `{}` (empty mapping).

Named arguments to pass into the `cassandra.cluster` class.

```python
    cassandra_options = {
        'cql_version': '3.2.1',
        'protocol_version': 3
    }
```

**Example configuration**

```python
    cassandra_servers = ['localhost']
cassandra_keyspace = 'celery'
cassandra_table = 'tasks'
cassandra_read_consistency = 'ONE'
cassandra_write_consistency = 'ONE'
cassandra_entry_ttl = 86400
```
S3 backend settings

Note: This s3 backend driver requires s3.
To install, use s3:

```bash
$ pip install celery[s3]
```

See Bundles for information on combining multiple extension requirements.

This backend requires the following configuration directives to be set.

**s3_access_key_id**

Default: None.

The s3 access key id. For example:

```python
s3_access_key_id = 'acces_key_id'
```

**s3_secret_access_key**

Default: None.

The s3 secret access key. For example:

```python
s3_secret_access_key = 'acces_secret_access_key'
```

**s3_bucket**

Default: None.

The s3 bucket name. For example:

```python
s3_bucket = 'bucket_name'
```

**s3_base_path**

Default: None.

A base path in the s3 bucket to use to store result keys. For example:

```python
s3_base_path = '/prefix'
```

**s3_endpoint_url**

Default: None.

A custom s3 endpoint url. Use it to connect to a custom self-hosted s3 compatible backend (Ceph, Scality…). For example:
s3_endpoint_url = 'https://s3.custom.url'

s3_region

Default: None.
The s3 aws region. For example:

s3_region = 'us-east-1'

Example configuration

s3_access_key_id = 's3-access-key-id'
s3_secret_access_key = 's3-secret-access-key'
s3_bucket = 'mybucket'
s3_base_path = '/celery_result_backend'
s3_endpoint_url = 'https://endpoint_url'

Azure Block Blob backend settings

To use AzureBlockBlob as the result backend you simply need to configure the result_backend setting with the correct URL.

The required URL format is azureblockblob:// followed by the storage connection string. You can find the storage connection string in the Access Keys pane of your storage account resource in the Azure Portal.

Example configuration

result_backend = azureblockblob://DefaultEndpointsProtocol=https;AccountName=somename;AccountKey=Lou...bzg==;EndpointSuffix=core.windows.net

azureblockblob_container_name

Default: celery.
The name for the storage container in which to store the results.

azureblockblob_retry_initial_backoff_sec

Default: 2.
The initial backoff interval, in seconds, for the first retry. Subsequent retries are attempted with an exponential strategy.

azureblockblob_retry_increment_base

Default: 2.
azureblockblob_retry_max_attempts

Default: 3.
The maximum number of retry attempts.

Elasticsearch backend settings

To use Elasticsearch as the result backend you simply need to configure the `result_backend` setting with the correct URL.

Example configuration

```
result_backend = 'elasticsearch://example.com:9200/index_name/doc_type'
```

elasticsearch_retry_on_timeout

Default: False
Should timeout trigger a retry on different node?

elasticsearch_max_retries

Default: 3.
Maximum number of retries before an exception is propagated.

elasticsearch_timeout

Default: 10.0 seconds.
Global timeout, used by the elasticsearch result backend.

Riak backend settings

Note: The Riak backend requires the riak library.

To install the this package use `pip`:

```
$ pip install celery[riak]
```

See Bundles for information on combining multiple extension requirements.

This backend requires the `result_backend` setting to be set to a Riak URL:

```
result_backend = 'riak://host:port/bucket'
```

For example:
result_backend = 'riak://localhost/celery'

is the same as:

result_backend = 'riak://'

The fields of the URL are defined as follows:

1. host
   Host name or IP address of the Riak server (e.g., 'localhost').

2. port
   Port to the Riak server using the protobuf protocol. Default is 8087.

3. bucket
   Bucket name to use. Default is celery. The bucket needs to be a string with ASCII characters only.

Alternatively, this backend can be configured with the following configuration directives.

**riak_backend_settings**

Default: {} (empty mapping).

This is a dict supporting the following keys:

- host
  The host name of the Riak server. Defaults to "localhost".
- port
  The port the Riak server is listening to. Defaults to 8087.
- bucket
  The bucket name to connect to. Defaults to “celery”.
- protocol
  The protocol to use to connect to the Riak server. This isn’t configurable via result_backend

**AWS DynamoDB backend settings**

**Note**: The Dynamodb backend requires the boto3 library.

To install this package use **pip**:

```
$ pip install celery[dynamodb]
```

See **Bundles** for information on combining multiple extension requirements.

This backend requires the result_backend setting to be set to a DynamoDB URL:

```python
result_backend = 'dynamodb://aws_access_key_id:aws_secret_access_key@region:port/table?read=n&write=m'
```
For example, specifying the AWS region and the table name:

```python
result_backend = 'dynamodb://@us-east-1/celery_results'
```

or retrieving AWS configuration parameters from the environment, using the default table name (celery) and specifying read and write provisioned throughput:

```python
result_backend = 'dynamodb://@/?read=5&write=5'
```

or using the downloadable version of DynamoDB locally:

```python
result_backend = 'dynamodb://@localhost:8000'
```

or using downloadable version or other service with conforming API deployed on any host:

```python
result_backend = 'dynamodb://@us-east-1'
dynamodb_endpoint_url = 'http://192.168.0.40:8000'
```

The fields of the DynamoDB URL in `result_backend` are defined as follows:

1. `aws_access_key_id` & `aws_secret_access_key`
   The credentials for accessing AWS API resources. These can also be resolved by the boto3 library from various sources, as described here.

2. `region`
   The AWS region, e.g. `us-east-1` or `localhost` for the Downloadable Version. See the boto3 library documentation for definition options.

3. `port`
   The listening port of the local DynamoDB instance, if you are using the downloadable version. If you have not specified the `region` parameter as `localhost`, setting this parameter has no effect.

4. `table`
   Table name to use. Default is `celery`. See the DynamoDB Naming Rules for information on the allowed characters and length.

5. `read` & `write`
   The Read & Write Capacity Units for the created DynamoDB table. Default is 1 for both read and write. More details can be found in the Provisioned Throughput documentation.

6. `ttl_seconds`
   Time-to-live (in seconds) for results before they expire. The default is to not expire results, while also leaving the DynamoDB table’s Time to Live settings untouched. If `ttl_seconds` is set to a positive value, results will expire after the specified number of seconds. Setting `ttl_seconds` to a negative value means not to expire results, and also to actively disable the DynamoDB table’s Time to Live setting. Note that trying to change a table’s Time to Live setting multiple times in quick succession will cause a throttling error. More details can be found in the DynamoDB TTL documentation.

**IronCache backend settings**

Note: The IronCache backend requires the iron_celery library:

To install this package use `pip`:
IronCache is configured via the URL provided in `result_backend`, for example:

```
result_backend = 'ironcache://project_id:token@
```

Or to change the cache name:

```
ironcache://project_id:token@/awesomecache
```

For more information, see: https://github.com/iron-io/iron_celery

**Couchbase backend settings**

**Note:** The Couchbase backend requires the couchbase library.

To install this package use pip:

```
$ pip install celery[couchbase]
```

See Bundles for instructions how to combine multiple extension requirements.

This backend can be configured via the `result_backend` set to a Couchbase URL:

```
result_backend = 'couchbase://username:password@host:port/bucket'
```

**couchbase_backend_settings**

Default: `{}` (empty mapping).

This is a dict supporting the following keys:

- **host**
  
  Host name of the Couchbase server. Defaults to `localhost`.

- **port**
  
  The port the Couchbase server is listening to. Defaults to `8091`.

- **bucket**
  
  The default bucket the Couchbase server is writing to. Defaults to `default`.

- **username**
  
  User name to authenticate to the Couchbase server as (optional).

- **password**
  
  Password to authenticate to the Couchbase server (optional).
ArangoDB backend settings

Note: The ArangoDB backend requires the pyArango library.
To install this package use pip:

```bash
$ pip install celery[arangodb]
```

See Bundles for instructions how to combine multiple extension requirements.

This backend can be configured via the `result_backend` set to a ArangoDB URL:

```python
result_backend = 'arangodb://username:password@host:port/database/collection'
```

**arangodb_backend_settings**

Default: `{}` (empty mapping).
This is a dict supporting the following keys:

- **host**
  Host name of the ArangoDB server. Defaults to localhost.

- **port**
  The port the ArangoDB server is listening to. Defaults to 8529.

- **database**
  The default database in the ArangoDB server is writing to. Defaults to celery.

- **collection**
  The default collection in the ArangoDB servers database is writing to. Defaults to celery.

- **username**
  User name to authenticate to the ArangoDB server as (optional).

- **password**
  Password to authenticate to the ArangoDB server (optional).

CosmosDB backend settings (experimental)

To use CosmosDB as the result backend, you simply need to configure the `result_backend` setting with the correct URL.

**Example configuration**

```python
result_backend =
    'cosmosdbsql://:{InsertAccountPrimaryKeyHere}@{InsertAccountNameHere}.documents.azure.com'
```
cosmosdbsql_database_name

Default: celerydb.
The name for the database in which to store the results.

cosmosdbsql_collection_name

Default: celerycol.
The name of the collection in which to store the results.

cosmosdbsql_consistency_level

Default: Session.
Represents the consistency levels supported for Azure Cosmos DB client operations.
Consistency levels by order of strength are: Strong, BoundedStaleness, Session, ConsistentPrefix and Eventual.

cosmosdbsql_max_retry_attempts

Default: 9.
Maximum number of retries to be performed for a request.

cosmosdbsql_max_retry_wait_time

Default: 30.
Maximum wait time in seconds to wait for a request while the retries are happening.

CouchDB backend settings

Note: The CouchDB backend requires the pycouchdb library:
To install this Couchbase package use pip:

```bash
$ pip install celery[couchdb]
```

See Bundles for information on combining multiple extension requirements.

This backend can be configured via the result_backend set to a CouchDB URL:

```
result_backend = 'couchdb://username:password@host:port/container'
```

The URL is formed out of the following parts:

- **username**
  User name to authenticate to the CouchDB server as (optional).
- **password**
Password to authenticate to the CouchDB server (optional).

- **host**
  
  Host name of the CouchDB server. Defaults to `localhost`.

- **port**
  
  The port the CouchDB server is listening to. Defaults to 8091.

- **container**
  
  The default container the CouchDB server is writing to. Defaults to `default`.

### File-system backend settings

This backend can be configured using a file URL, for example:

```
CELERY_RESULT_BACKEND = 'file:///var/celery/results'
```

The configured directory needs to be shared and writable by all servers using the backend.

If you’re trying Celery on a single system you can simply use the backend without any further configuration. For larger clusters you could use NFS, GlusterFS, CIFS, HDFS (using FUSE), or any other file-system.

### Consul K/V store backend settings

The Consul backend can be configured using a URL, for example:

```
CELERY_RESULT_BACKEND = 'consul://localhost:8500/'
```

The backend will storage results in the K/V store of Consul as individual keys.

The backend supports auto expire of results using TTLs in Consul.

### Message Routing

**task_queues**

Default: `None` (queue taken from default queue settings).

Most users will not want to specify this setting and should rather use the `automatic routing facilities`.

If you really want to configure advanced routing, this setting should be a list of `kombu.Queue` objects the worker will consume from.

Note that workers can be overridden this setting via the `-Q` option, or individual queues from this list (by name) can be excluded using the `-X` option.

Also see `Basics` for more information.

The default is a queue/exchange/binding key of `celery`, with exchange type `direct`.

See also `task_routes`
**task_routes**

Default: None.

A list of routers, or a single router used to route tasks to queues. When deciding the final destination of a task the routers are consulted in order.

A router can be specified as either:

- A function with the signature \( (\text{name}, \text{args}, \text{kwargs}, \text{options}, \text{task=None}, **\text{kwargs}) \)
- A string providing the path to a router function.
- **A dict containing router specification:** Will be converted to a celery.routes.MapRoute instance.
- **A list of (pattern, route) tuples:** Will be converted to a celery.routes.MapRoute instance.

Examples:

```python
from celery import tasks

task_routes = {
    'celery.ping': 'default',
    'mytasks.add': 'cpu-bound',
    'feed.tasks.*': 'feeds', # <-- glob pattern
    re.compile(r'\(image|video)\..*'): 'media', # <-- regex
    'video.encode': {
        'queue': 'video',
        'exchange': 'media',
        'routing_key': 'media.video.encode',
    },
}
```

task_routes = ('myapp.tasks.route_task', ('celery.ping': 'default'))

Where `myapp.tasks.route_task` could be:

```python
def route_task(self, name, args, kwargs, options, task=None, **kw):
    if task == 'celery.ping':
        return {'queue': 'default'}
```

`route_task` may return a string or a dict. A string then means it’s a queue name in `task_queues`, a dict means it’s a custom route.

When sending tasks, the routers are consulted in order. The first router that doesn’t return `None` is the route to use. The message options is then merged with the found route settings, where the task’s settings have priority.

Example if `apply_async()` has these arguments:

```python
Task.apply_async(immediate=False, exchange='video',
                 routing_key='video.compress')
```

and a router returns:

```python
{'immediate': True, 'exchange': 'urgent'}
```

the final message options will be:

```python
immediate=False, exchange='video', routing_key='video.compress'
```

(and any default message options defined in the Task class)

Values defined in `task_routes` have precedence over values defined in `task_queues` when merging the two.

---

**3.3. User Guide**

217
With the follow settings:

```python
task_queues = {
    'cpubound': {
        'exchange': 'cpubound',
        'routing_key': 'cpubound',
    },
}

task_routes = {
    'tasks.add': {
        'queue': 'cpubound',
        'routing_key': 'tasks.add',
        'serializer': 'json',
    },
}
```

The final routing options for `tasks.add` will become:

```python
{'exchange': 'cpubound',
 'routing_key': 'tasks.add',
 'serializer': 'json'}
```

See `Routers` for more examples.

**task_queue_ha_policy**

**brokers** RabbitMQ

Default: None.

This will set the default HA policy for a queue, and the value can either be a string (usually `all`):

```python
task_queue_ha_policy = 'all'
```

Using `all` will replicate the queue to all current nodes, Or you can give it a list of nodes to replicate to:

```python
task_queue_ha_policy = ['rabbit@host1', 'rabbit@host2']
```

Using a list will implicitly set `x-ha-policy` to `nodes` and `x-ha-policy-params` to the given list of nodes. See [http://www.rabbitmq.com/ha.html](http://www.rabbitmq.com/ha.html) for more information.

**task_queue_max_priority**

**brokers** RabbitMQ

Default: None.

See `RabbitMQ Message Priorities`.

**task_default_priority**

**brokers** RabbitMQ, Redis
Default: None.
See *RabbitMQ Message Priorities*.

**task_inherit_parent_priority**

**brokers** RabbitMQ

Default: False.
If enabled, child tasks will inherit priority of the parent task.

```python
# The last task in chain will also have priority set to 5.
chain = celery.chain(add.s(2) | add.s(2).set(priority=5) | add.s(3))
```

Priority inheritance also works when calling child tasks from a parent task with `delay` or `apply_async`.
See *RabbitMQ Message Priorities*.

**worker_direct**

Default: Disabled.
This option enables so that every worker has a dedicated queue, so that tasks can be routed to specific workers.
The queue name for each worker is automatically generated based on the worker hostname and a `.dq` suffix, using the `C.dq` exchange.
For example the queue name for the worker with node name `w1@example.com` becomes:

```
wl@example.com.dq
```

Then you can route the task to the task by specifying the hostname as the routing key and the `C.dq` exchange:

```python
task_routes = {
    'tasks.add': {'exchange': 'C.dq', 'routing_key': 'wl@example.com'}
}
```

**task_create_missing_queues**

Default: Enabled.
If enabled (default), any queues specified that aren’t defined in `task_queues` will be automatically created. See *Automatic routing*.

**task_default_queue**

Default: "celery".
The name of the default queue used by `apply_async` if the message has no route or no custom queue has been specified.
This queue must be listed in `task_queues`. If `task_queues` isn’t specified then it’s automatically created containing one queue entry, where this name is used as the name of that queue.

See also:
* Changing the name of the default queue
**task_default_exchange**

Default: Uses the value set for `task_default_queue`.
Name of the default exchange to use when no custom exchange is specified for a key in the `task_queues` setting.

**task_default_exchange_type**

Default: "direct".
Default exchange type used when no custom exchange type is specified for a key in the `task_queues` setting.

**task_default_routing_key**

Default: Uses the value set for `task_default_queue`.
The default routing key used when no custom routing key is specified for a key in the `task_queues` setting.

**task_default_delivery_mode**

Default: "persistent".
Can be `transient` (messages not written to disk) or `persistent` (written to disk).

**Broker Settings**

**broker_url**

Default: "amqp://"
Default broker URL. This must be a URL in the form of:

```
transport://userid:password@hostname:port/virtual_host
```

Only the scheme part (`transport://`) is required, the rest is optional, and defaults to the specific transports default values.

The transport part is the broker implementation to use, and the default is `amqp`, (uses `librabbitmq` if installed or falls back to `pyamqp`). There are also other choices available, including; `redis://`, `sqs://`, and `qpid://`.

The scheme can also be a fully qualified path to your own transport implementation:

```
broker_url = 'proj.transports.MyTransport://localhost'
```

More than one broker URL, of the same transport, can also be specified. The broker URLs can be passed in as a single string that’s semicolon delimited:

```
broker_url = 
    'transport://userid:password@hostname:port//;transport://userid:password@hostname:port//'
```

Or as a list:
broker_url = [
    'transport://userid:password@localhost:port//',
    'transport://userid:password@hostname:port//'
]

The brokers will then be used in the `broker_failover_strategy`.
See URLs in the Kombu documentation for more information.

**broker_read_url / broker_write_url**

Default: Taken from `broker_url`.
These settings can be configured, instead of `broker_url` to specify different connection parameters for broker connections used for consuming and producing.

Example:

```python
broker_read_url = 'amqp://user:pass@broker.example.com:56721'
broker_write_url = 'amqp://user:pass@broker.example.com:56722'
```

Both options can also be specified as a list for failover alternates, see `broker_url` for more information.

**broker_failover_strategy**

Default: "round-robin".
Default failover strategy for the broker Connection object. If supplied, may map to a key in ‘kombu.connection.failover_strategies’, or be a reference to any method that yields a single item from a supplied list.

Example:

```python
# Random failover strategy
def random_failover_strategy(servers):
    it = list(servers)  # don't modify callers list
    shuffle = random.shuffle
    for _ in repeat(None):
        shuffle(it)
        yield it[0]

broker_failover_strategy = random_failover_strategy
```

**broker_heartbeat**

`transports supported` pyamqp
Default: 120.0 (negotiated by server).
Note: This value is only used by the worker, clients do not use a heartbeat at the moment.
It’s not always possible to detect connection loss in a timely manner using TCP/IP alone, so AMQP defines something called heartbeats that’s is used both by the client and the broker to detect if a connection was closed.

3.3. User Guide
If the heartbeat value is 10 seconds, then the heartbeat will be monitored at the interval specified by the `broker_heartbeat_checkrate` setting (by default this is set to double the rate of the heartbeat value, so for the 10 seconds, the heartbeat is checked every 5 seconds).

**broker_heartbeat_checkrate**

<table>
<thead>
<tr>
<th>transports supported</th>
<th>pyamqp</th>
</tr>
</thead>
</table>

Default: 2.0.

At intervals the worker will monitor that the broker hasn’t missed too many heartbeats. The rate at which this is checked is calculated by dividing the `broker_heartbeat` value with this value, so if the heartbeat is 10.0 and the rate is the default 2.0, the check will be performed every 5 seconds (twice the heartbeat sending rate).

**broker_use_ssl**

<table>
<thead>
<tr>
<th>transports supported</th>
<th>pyamqp, redis</th>
</tr>
</thead>
</table>

Default: Disabled.

Toggles SSL usage on broker connection and SSL settings.

The valid values for this option vary by transport.

**pyamqp**

If `True` the connection will use SSL with default SSL settings. If set to a dict, will configure SSL connection according to the specified policy. The format used is Python’s `ssl.wrap_socket()` options.

Note that SSL socket is generally served on a separate port by the broker.

Example providing a client cert and validating the server cert against a custom certificate authority:

```python
import ssl

broker_use_ssl = {
    'keyfile': '/var/ssl/private/worker-key.pem',
    'certfile': '/var/ssl/amqp-server-cert.pem',
    'ca_certs': '/var/ssl/myca.pem',
    'cert_reqs': ssl.CERT_REQUIRED
}
```

**Warning:** Be careful using `broker_use_ssl=True`. It’s possible that your default configuration won’t validate the server cert at all. Please read Python SSL module security considerations.

**redis**

The setting must be a dict with the following keys:

- `ssl_cert_reqs` (required): one of the `SSLCertPolicy.verify_mode` values:
  - `ssl.CERT_NONE`
  - `ssl.CERT_OPTIONAL`
- `ssl.CERT_REQUIRED`
  - `ssl_ca_certs` (optional): path to the CA certificate
  - `ssl_certfile` (optional): path to the client certificate
  - `ssl_keyfile` (optional): path to the client key

**broker_pool_limit**

New in version 2.3.
Default: 10.
The maximum number of connections that can be open in the connection pool.
The pool is enabled by default since version 2.5, with a default limit of ten connections. This number can be tweaked depending on the number of threads/green-threads (eventlet/gevent) using a connection. For example running eventlet with 1000 greenlets that use a connection to the broker, contention can arise and you should consider increasing the limit.
If set to `None` or 0 the connection pool will be disabled and connections will be established and closed for every use.

**broker_connection_timeout**

Default: 4.0.
The default timeout in seconds before we give up establishing a connection to the AMQP server. This setting is disabled when using gevent.

**Note:** The broker connection timeout only applies to a worker attempting to connect to the broker. It does not apply to producer sending a task, see `broker_transport_options` for how to provide a timeout for that situation.

**broker_connection_retry**

Default: Enabled.
Automatically try to re-establish the connection to the AMQP broker if lost.
The time between retries is increased for each retry, and is not exhausted before `broker_connection_max_retries` is exceeded.

**broker_connection_max_retries**

Default: 100.
Maximum number of retries before we give up re-establishing a connection to the AMQP broker.
If this is set to 0 or `None`, we’ll retry forever.
**broker_login_method**

Default: "AMQPLAIN".
Set custom amqp login method.

**broker_transport_options**

New in version 2.2.
Default: {} (empty mapping).
A dict of additional options passed to the underlying transport.
See your transport user manual for supported options (if any).
Example setting the visibility timeout (supported by Redis and SQS transports):

```python
broker_transport_options = {'visibility_timeout': 18000}  # 5 hours
```

Example setting the producer connection maximum number of retries (so producers won’t retry forever if the broker isn’t available at the first task execution):

```python
broker_transport_options = {'max_retries': 5}
```

**Worker**

**imports**

Default: [] (empty list).
A sequence of modules to import when the worker starts.
This is used to specify the task modules to import, but also to import signal handlers and additional remote control commands, etc.
The modules will be imported in the original order.

**include**

Default: [] (empty list).
Exact same semantics as imports, but can be used as a means to have different import categories.
The modules in this setting are imported after the modules in imports.

**worker_concurrency**

Default: Number of CPU cores.
The number of concurrent worker processes/threads/green threads executing tasks.
If you’re doing mostly I/O you can have more processes, but if mostly CPU-bound, try to keep it close to the number of CPUs on your machine. If not set, the number of CPUs/cores on the host will be used.
worker_prefetch_multiplier

Default: 4.

How many messages to prefetch at a time multiplied by the number of concurrent processes. The default is 4 (four messages for each process). The default setting is usually a good choice, however – if you have very long running tasks waiting in the queue and you have to start the workers, note that the first worker to start will receive four times the number of messages initially. Thus the tasks may not be fairly distributed to the workers.

To disable prefetching, set worker_prefetch_multiplier to 1. Changing that setting to 0 will allow the worker to keep consuming as many messages as it wants.

For more on prefetching, read Prefetch Limits

---

**Note:** Tasks with ETA/countdown aren’t affected by prefetch limits.

---

worker_lost_wait

Default: 10.0 seconds.

In some cases a worker may be killed without proper cleanup, and the worker may have published a result before terminating. This value specifies how long we wait for any missing results before raising a WorkerLostError exception.

---

worker_max_tasks_per_child

Maximum number of tasks a pool worker process can execute before it’s replaced with a new one. Default is no limit.

---

worker_max_memory_per_child

Default: No limit. Type: int (kilobytes)

Maximum amount of resident memory, in kilobytes, that may be consumed by a worker before it will be replaced by a new worker. If a single task causes a worker to exceed this limit, the task will be completed, and the worker will be replaced afterwards.

Example:

```
worker_max_memory_per_child = 12000  # 12MB
```

---

worker_disable_rate_limits

Default: Disabled (rate limits enabled).

Disable all rate limits, even if tasks has explicit rate limits set.

---

worker_state_db

Default: None.
Name of the file used to stores persistent worker state (like revoked tasks). Can be a relative or absolute path, but be aware that the suffix `.db` may be appended to the file name (depending on Python version).
Can also be set via the `celery worker --statedb` argument.

**worker_timer_precision**

Default: 1.0 seconds.
Set the maximum time in seconds that the ETA scheduler can sleep between rechecking the schedule.
Setting this value to 1 second means the schedulers precision will be 1 second. If you need near millisecond precision you can set this to 0.1.

**worker_enable_remote_control**

Default: Enabled by default.
Specify if remote control of the workers is enabled.

**worker_proc_alive_timeout**

Default: 4.0.
The timeout in seconds (int/float) when waiting for a new worker process to start up.

**Events**

**worker_send_task_events**

Default: Disabled by default.
Send task-related events so that tasks can be monitored using tools like Flower. Sets the default value for the workers `-E` argument.

**task_send_sent_event**

New in version 2.2.
Default: Disabled by default.
If enabled, a `task-sent` event will be sent for every task so tasks can be tracked before they’re consumed by a worker.

**event_queue_ttl**

**transports supported** amqp
Default: 5.0 seconds.
Message expiry time in seconds (int/float) for when messages sent to a monitor clients event queue is deleted (`x-message-ttl`)
For example, if this value is set to 10 then a message delivered to this queue will be deleted after 10 seconds.

**event_queue_expires**

Transports supported: amqp

Default: 60.0 seconds.

Expiry time in seconds (int/float) for when after a monitor clients event queue will be deleted (x.expires).

**event_queue_prefix**

Default: "celeryev".

The prefix to use for event receiver queue names.

**event_exchange**

Default: "celeryev".

Name of the event exchange.

**Warning:** This option is in experimental stage, please use it with caution.

**event_serializer**

Default: "json".

Message serialization format used when sending event messages.

See also:

Serializers.

**Remote Control Commands**

**Note:** To disable remote control commands see the worker_enable_remote_control setting.

**control_queue_ttl**

Default: 300.0

Time in seconds, before a message in a remote control command queue will expire.

If using the default of 300 seconds, this means that if a remote control command is sent and no worker picks it up within 300 seconds, the command is discarded.

This setting also applies to remote control reply queues.
control_queue_expires

Default: 10.0
Time in seconds, before an unused remote control command queue is deleted from the broker.
This setting also applies to remote control reply queues.

control_exchange

Default: "celery".
Name of the control command exchange.

**Warning:** This option is in experimental stage, please use it with caution.

Logging

worker_hijack_root_logger

New in version 2.2.
Default: Enabled by default (hijack root logger).
By default any previously configured handlers on the root logger will be removed. If you want to customize your own
logging handlers, then you can disable this behavior by setting `worker_hijack_root_logger = False`.

**Note:** Logging can also be customized by connecting to the `celery.signals.setup_logging` signal.

worker_log_color

Default: Enabled if app is logging to a terminal.
Enables/disables colors in logging output by the Celery apps.

worker_log_format

Default:

```
"%(asctime)s: %(levelname)s/%(processName)s] %(message)s"
```

The format to use for log messages.
See the Python `logging` module for more information about log formats.
worker_task_log_format

Default:

```
"[%(asctime)s: %(levelname)s/%(processName)s]
   %(task_name)s(%(task_id)s)] %(message)s"
```

The format to use for log messages logged in tasks.
See the Python `logging` module for more information about log formats.

worker_redirect_stdouts

Default: Enabled by default.
If enabled `stdout` and `stderr` will be redirected to the current logger.
Used by `celery worker` and `celery beat`.

worker_redirect_stdouts_level

Default: WARNING.
The log level output to `stdout` and `stderr` is logged as. Can be one of DEBUG, INFO, WARNING, ERROR, or CRITICAL.

Security

security_key

Default: None.
New in version 2.5.
The relative or absolute path to a file containing the private key used to sign messages when `Message Signing` is used.

security_certificate

Default: None.
New in version 2.5.
The relative or absolute path to an X.509 certificate file used to sign messages when `Message Signing` is used.

security_cert_store

Default: None.
New in version 2.5.
The directory containing X.509 certificates used for `Message Signing`. Can be a glob with wild-cards, (for example `/etc/certs/*/pem`).
security_digest

Default: sha256.
New in version 4.3.
A cryptography digest used to sign messages when Message Signing is used. https://cryptography.io/en/latest/hazmat/primitives/cryptographic-hashes/#module-cryptography.hazmat.primitives.hashes

Custom Component Classes (advanced)

worker_pool

Default: "prefork" (celery.concurrency.prefork:TaskPool).
Name of the pool class used by the worker.

Eventlet/Gevent

Never use this option to select the eventlet or gevent pool. You must use the \-P option to celery worker instead, to ensure the monkey patches aren’t applied too late, causing things to break in strange ways.

worker_pool_restarts

Default: Disabled by default.
If enabled the worker pool can be restarted using the pool_restart remote control command.

worker_autoscaler

New in version 2.2.
Default: "celery.worker.autoscale:Autoscaler".
Name of the autoscaler class to use.

worker_consumer

Default: "celery.worker.consumer:Consumer".
Name of the consumer class used by the worker.

worker_timer

Default: "kombu.asynchronous.hub.timer:Timer".
Name of the ETA scheduler class used by the worker. Default is or set by the pool implementation.
Beat Settings (celery beat)

**beat_schedule**

Default: `{}` (empty mapping).
The periodic task schedule used by `beat`. See *Entries*.

**beat_scheduler**

Default: "celery.beat:PersistentScheduler".
The default scheduler class. May be set to "django_celery_beat.schedulers:DatabaseScheduler" for instance, if used alongside django-celery-beat extension.
Can also be set via the `celery beat -S` argument.

**beat_schedule_filename**

Default: "celerybeat-schedule".
Name of the file used by `PersistentScheduler` to store the last run times of periodic tasks. Can be a relative or absolute path, but be aware that the suffix `.db` may be appended to the file name (depending on Python version).
Can also be set via the `celery beat --schedule` argument.

**beat_sync_every**

Default: 0.
The number of periodic tasks that can be called before another database sync is issued. A value of 0 (default) means sync based on timing - default of 3 minutes as determined by scheduler.sync_every. If set to 1, beat will call sync after every task message sent.

**beat_max_loop_interval**

Default: 0.
The maximum number of seconds `beat` can sleep between checking the schedule.
The default for this value is scheduler specific. For the default Celery beat scheduler the value is 300 (5 minutes), but for the django-celery-beat database scheduler it’s 5 seconds because the schedule may be changed externally, and so it must take changes to the schedule into account.
Also when running Celery beat embedded (-B) on Jython as a thread the max interval is overridden and set to 1 so that it’s possible to shut down in a timely manner.

### 3.3.18 Documenting Tasks with Sphinx

This document describes how auto-generate documentation for Tasks using Sphinx.
celery.contrib.sphinx

Sphinx documentation plugin used to document tasks.

Introduction

Usage

Add the extension to your docs/conf.py configuration module:

```python
extensions = (...,
    'celery.contrib.sphinx')
```

If you’d like to change the prefix for tasks in reference documentation then you can change the celery_task_prefix configuration value:

```python
celery_task_prefix = '{(task)}' # < default
```

With the extension installed autodoc will automatically find task decorated objects (e.g. when using the automodule directive) and generate the correct (as well as add a (task) prefix), and you can also refer to the tasks using :task:proj.tasks.add syntax.

Use .. autotask:: to alternatively manually document a task.

```python
class celery.contrib.sphinx.TaskDirective
    (name, arguments, options, content, linenos, content_offset, block_text, state, state_machine)

    Sphinx task directive.

    get_signature_prefix(sig)
        May return a prefix to put before the object name in the signature.

class celery.contrib.sphinx.TaskDocumenter
    (directive, name, indent="")

    Document task definitions.

    classmethod can_document_member
        (member, membername, isattr, parent)

        Called to see if a member can be documented by this documenter.

    check_module()
        Check if self.object is really defined in the module given by self.modname.

    document_members
        (all_members=False)

        Generate reST for member documentation.

        If all_members is True, do all members, else those given by self.options.members.

    format_args()
        Format the argument signature of self.object.

        Should return None if the object does not have a signature.

celery.contrib.sphinx.autodoc_skip_member_handler
    (app, what, name, obj, skip, options)

    Handler for autodoc-skip-member event.

celery.contrib.sphinx.setup
    (app)

    Setup Sphinx extension.
```
3.4 Django

Release 4.4  
Date Dec 16, 2019

3.4.1 First steps with Django

Using Celery with Django

Note: Previous versions of Celery required a separate library to work with Django, but since 3.1 this is no longer the case. Django is supported out of the box now so this document only contains a basic way to integrate Celery and Django. You’ll use the same API as non-Django users so you’re recommended to read the First Steps with Celery tutorial first and come back to this tutorial. When you have a working example you can continue to the Next Steps guide.

Note: Celery 4.0 supports Django 1.8 and newer versions. Please use Celery 3.1 for versions older than Django 1.8.

To use Celery with your Django project you must first define an instance of the Celery library (called an “app”)

If you have a modern Django project layout like:

```
- proj/
  - manage.py
  - proj/
    - __init__.py
    - settings.py
    - urls.py
```

then the recommended way is to create a new `proj/proj/celery.py` module that defines the Celery instance:

```
from __future__ import absolute_import, unicode_literals
import os
from celery import Celery
# set the default Django settings module for the 'celery' program.
os.environ.setdefault('DJANGO_SETTINGS_MODULE', 'proj.settings')
app = Celery('proj')
# Using a string here means the worker doesn't have to serialize
# the configuration object to child processes.
# - namespace='CELERY' means all celery-related configuration keys
# should have a 'CELERY_' prefix.
app.config_from_object('django.conf:settings', namespace='CELERY')
# Load task modules from all registered Django app configs.
app.autodiscover_tasks()
```

(continues on next page)
Then you need to import this app in your `proj/proj/__init__.py` module. This ensures that the app is loaded when Django starts so that the `@shared_task` decorator (mentioned later) will use it:

```python
from __future__ import absolute_import, unicode_literals

# This will make sure the app is always imported when
# Django starts so that shared_task will use this app.
from .celery import app as celery_app
__all__ = ('celery_app',)
```

Note that this example project layout is suitable for larger projects, for simple projects you may use a single contained module that defines both the app and tasks, like in the First Steps with Celery tutorial.

Let’s break down what happens in the first module, first we import absolute imports from the future, so that our `celery.py` module won’t clash with the library:

```python
from __future__ import absolute_import
```

Then we set the default `DJANGO_SETTINGS_MODULE` environment variable for the `celery` command-line program:

```python
os.environ.setdefault('DJANGO_SETTINGS_MODULE', 'proj.settings')
```

You don’t need this line, but it saves you from always passing in the settings module to the `celery` program. It must always come before creating the app instances, as is what we do next:

```python
app = Celery('proj')
```

This is our instance of the library, you can have many instances but there’s probably no reason for that when using Django.

We also add the Django settings module as a configuration source for Celery. This means that you don’t have to use multiple configuration files, and instead configure Celery directly from the Django settings; but you can also separate them if wanted.

```python
app.config_from_object('django.conf:settings', namespace='CELERY')
```

The uppercase name-space means that all `Celery configuration options` must be specified in uppercase instead of lowercase, and start with `CELERY_`, so for example the `task_always_eager` setting becomes `CELERY_TASK_ALWAYS_EAGER`, and the `broker_url` setting becomes `CELERY_BROKER_URL`. This also applies to the workers settings, for instance, the `worker_concurrency` setting becomes `CELERY_WORKER_CONCURRENCY`.

You can pass the settings object directly instead, but using a string is better since then the worker doesn’t have to serialize the object. The `CELERY_` namespace is also optional, but recommended (to prevent overlap with other Django settings).

Next, a common practice for reusable apps is to define all tasks in a separate `tasks.py` module, and Celery does have a way to auto-discover these modules:
app.autodiscover_tasks()

With the line above Celery will automatically discover tasks from all of your installed apps, following the `tasks.py` convention:

```
- app1/
  - tasks.py
  - models.py
- app2/
  - tasks.py
  - models.py
```

This way you don’t have to manually add the individual modules to the `CELERY_IMPORTS` setting.

Finally, the `debug_task` example is a task that dumps its own request information. This is using the new `bind=True` task option introduced in Celery 3.1 to easily refer to the current task instance.

### Using the @shared_task decorator

The tasks you write will probably live in reusable apps, and reusable apps cannot depend on the project itself, so you also cannot import your app instance directly.

The `@shared_task` decorator lets you create tasks without having any concrete app instance:

**demoapp/tasks.py**:

```python
# Create your tasks here
from __future__ import absolute_import, unicode_literals
from celery import shared_task
from demoapp.models import Widget

@shared_task
def add(x, y):
    return x + y

@shared_task
def mul(x, y):
    return x * y

@shared_task
def xsum(numbers):
    return sum(numbers)

@shared_task
def count_widgets():
    return Widget.objects.count()

@shared_task
def rename_widget(widget_id, name):
    w = Widget.objects.get(id=widget_id)
```

(continues on next page)
See also:
You can find the full source code for the Django example project at: https://github.com/celery/celery/tree/master/examples/django/

Relative Imports
You have to be consistent in how you import the task module. For example, if you have `project.app` in `INSTALLED_APPS`, then you must also import the tasks from `project.app` or else the names of the tasks will end up being different.

See Automatic naming and relative imports

Extensions

django-celery-results - Using the Django ORM/Cache as a result backend

The `django-celery-results` extension provides result backends using either the Django ORM, or the Django Cache framework.

To use this with your project you need to follow these steps:

1. Install the `django-celery-results` library:
   
   ```bash
   $ pip install django-celery-results
   ```

2. Add `django_celery_results` to `INSTALLED_APPS` in your Django project’s `settings.py`:
   
   ```python
   INSTALLED_APPS = (
       ...
       'django_celery_results',
   )
   ```

   Note that there is no dash in the module name, only underscores.

3. Create the Celery database tables by performing a database migrations:
   
   ```bash
   $ python manage.py migrate django_celery_results
   ```

4. Configure Celery to use the `django-celery-results` backend.
   
   Assuming you are using Django’s `settings.py` to also configure Celery, add the following settings:
   
   ```python
   CELERY_RESULT_BACKEND = 'django-db'
   ```

   For the cache backend you can use:
   
   ```python
   CELERY_CACHE_BACKEND = 'django-cache'
   ```

   We can also use the cache defined in the `CACHES` setting in django.
Celery Documentation, Release 4.4.0

# celery setting.
CELERY_CACHE_BACKEND = 'default'

# django setting.
CACHES = {
    'default': {
        'BACKEND': 'django.core.cache.backends.db.DatabaseCache',
        'LOCATION': 'my_cache_table',
    }
}

For additional configuration options, view the Task result backend settings reference.

django-celery-beat - Database-backed Periodic Tasks with Admin interface.

See Using custom scheduler classes for more information.

Starting the worker process

In a production environment you’ll want to run the worker in the background as a daemon - see Daemonization - but for testing and development it is useful to be able to start a worker instance by using the celery worker manage command, much as you’d use Django’s manage.py runserver:

$ celery -A proj worker -l info

For a complete listing of the command-line options available, use the help command:

$ celery help

Known Issues

CONN_MAX_AGE other than zero is known to cause issues according to bug #4878. Until this is fixed, please set

CONN_MAX_AGE to zero.

Where to go from here

If you want to learn more you should continue to the Next Steps tutorial, and after that you can study the User Guide.

3.5 Contributing

Welcome!

This document is fairly extensive and you aren’t really expected to study this in detail for small contributions;

    The most important rule is that contributing must be easy and that the community is friendly and not nitpicking on details, such as coding style.

If you’re reporting a bug you should read the Reporting bugs section below to ensure that your bug report contains enough information to successfully diagnose the issue, and if you’re contributing code you should try to mimic the conventions you see surrounding the code you’re working on, but in the end all patches will be cleaned up by the person merging the changes so don’t worry too much.

3.5.1 Community Code of Conduct

The goal is to maintain a diverse community that’s pleasant for everyone. That’s why we would greatly appreciate it if everyone contributing to and interacting with the community also followed this Code of Conduct.

The Code of Conduct covers our behavior as members of the community, in any forum, mailing list, wiki, website, Internet relay chat (IRC), public meeting or private correspondence.

Be considerate

Your work will be used by other people, and you in turn will depend on the work of others. Any decision you take will affect users and colleagues, and we expect you to take those consequences into account when making decisions. Even if it’s not obvious at the time, our contributions to Celery will impact the work of others. For example, changes to code, infrastructure, policy, documentation and translations during a release may negatively impact others’ work.

Be respectful

The Celery community and its members treat one another with respect. Everyone can make a valuable contribution to Celery. We may not always agree, but disagreement is no excuse for poor behavior and poor manners. We might all experience some frustration now and then, but we cannot allow that frustration to turn into a personal attack. It’s important to remember that a community where people feel uncomfortable or threatened isn’t a productive one. We expect members of the Celery community to be respectful when dealing with other contributors as well as with people outside the Celery project and with users of Celery.

Be collaborative

Collaboration is central to Celery and to the larger free software community. We should always be open to collaboration. Your work should be done transparently and patches from Celery should be given back to the community when they’re made, not just when the distribution releases. If you wish to work on new code for existing upstream projects, at least keep those projects informed of your ideas and progress. It may not be possible to get consensus from upstream, or even from your colleagues about the correct implementation for an idea, so don’t feel obliged to have that agreement before you begin, but at least keep the outside world informed of your work, and publish your work in a way that allows outsiders to test, discuss, and contribute to your efforts.

When you disagree, consult others

Disagreements, both political and technical, happen all the time and the Celery community is no exception. It’s important that we resolve disagreements and differing views constructively and with the help of the community and community process. If you really want to go a different way, then we encourage you to make a derivative distribution or alternate set of packages that still build on the work we’ve done to utilize as common of a core as possible.

When you’re unsure, ask for help

Nobody knows everything, and nobody is expected to be perfect. Asking questions avoids many problems down the road, and so questions are encouraged. Those who are asked questions should be responsive and helpful. However, when asking a question, care must be taken to do so in an appropriate forum.

Step down considerately

Developers on every project come and go and Celery is no different. When you leave or disengage from the project, in whole or in part, we ask that you do so in a way that minimizes disruption to the project. This means you should tell people you’re leaving and take the proper steps to ensure that others can pick up where you left off.

3.5.2 Reporting Bugs
Security

You must never report security related issues, vulnerabilities or bugs including sensitive information to the bug tracker, or elsewhere in public. Instead sensitive bugs must be sent by email to security@celeryproject.org.

If you’d like to submit the information encrypted our PGP key is:

```plaintext

Other bugs

Bugs can always be described to the Mailing list, but the best way to report an issue and to ensure a timely response is to use the issue tracker.

1) Create a GitHub account.

You need to create a GitHub account to be able to create new issues and participate in the discussion.

2) Determine if your bug is really a bug.

You shouldn’t file a bug if you’re requesting support. For that you can use the Mailing list, or IRC. If you still need support you can open a github issue, please prepend the title with [QUESTION].

3) Make sure your bug hasn’t already been reported.

Search through the appropriate Issue tracker. If a bug like yours was found, check if you have new information that could be reported to help the developers fix the bug.

4) Check if you’re using the latest version.

The best way to report an issue to the developer is to check if you’re using the latest version.
A bug could be fixed by some other improvements and fixes - it might not have an existing report in the bug tracker. Make sure you’re using the latest releases of celery, billiard, kombu, amqp, and vine.

5) Collect information about the bug.

To have the best chance of having a bug fixed, we need to be able to easily reproduce the conditions that caused it. Most of the time this information will be from a Python traceback message, though some bugs might be in design, spelling or other errors on the website/docs/code.

A) If the error is from a Python traceback, include it in the bug report.

B) We also need to know what platform you’re running (Windows, macOS, Linux, etc.), the version of your Python interpreter, and the version of Celery, and related packages that you were running when the bug occurred.

C) If you’re reporting a race condition or a deadlock, tracebacks can be hard to get or might not be that useful. Try to inspect the process to get more diagnostic data. Some ideas:

   - Enable Celery’s *breakpoint signal* and use it to inspect the process’s state. This will allow you to open a *pdb* session.
   - Collect tracing data using *strace* (Linux), :command:`dtruss` (macOS), and *ktrace* (BSD), *ltrace*, and *lsof*.

D) Include the output from the *celery report* command:

   $ celery -A proj report

   This will also include your configuration settings and it will try to remove values for keys known to be sensitive, but make sure you also verify the information before submitting so that it doesn’t contain confidential information like API tokens and authentication credentials.

E) Your issue might be tagged as *Needs Test Case*. A test case represents all the details needed to reproduce what your issue is reporting. A test case can be some minimal code that reproduces the issue or detailed instructions and configuration values that reproduces said issue.

6) Submit the bug.

By default *GitHub* will email you to let you know when new comments have been made on your bug. In the event you’ve turned this feature off, you should check back on occasion to ensure you don’t miss any questions a developer trying to fix the bug might ask.

### Issue Trackers

Bugs for a package in the Celery ecosystem should be reported to the relevant issue tracker.

- celery: https://github.com/celery/celery/issues/
- kombu: https://github.com/celery/kombu/issues
- amqp: https://github.com/celery/py-amqp/issues
- vine: https://github.com/celery/vine/issues
- librabbitmq: https://github.com/celery/librabbitmq/issues
- django-celery-beat: https://github.com/celery/django-celery-beat/issues
- django-celery-results: https://github.com/celery/django-celery-results/issues

If you’re unsure of the origin of the bug you can ask the *Mailing list*, or just use the Celery issue tracker.
3.5.3 Contributors guide to the code base

There’s a separate section for internal details, including details about the code base and a style guide.
Read *Contributors Guide to the Code* for more!

3.5.4 Versions

Version numbers consists of a major version, minor version and a release number. Since version 2.1.0 we use the versioning semantics described by SemVer: [http://semver.org](http://semver.org).

Stable releases are published at PyPI while development releases are only available in the GitHub git repository as tags. All version tags starts with “v”, so version 0.8.0 has the tag v0.8.0.

3.5.5 Branches

Current active version branches:

- dev (which git calls “master”) ([https://github.com/celery/celery/tree/master](https://github.com/celery/celery/tree/master))
- 4.2 ([https://github.com/celery/celery/tree/4.2](https://github.com/celery/celery/tree/4.2))
- 4.1 ([https://github.com/celery/celery/tree/4.1](https://github.com/celery/celery/tree/4.1))
- 3.1 ([https://github.com/celery/celery/tree/3.1](https://github.com/celery/celery/tree/3.1))

You can see the state of any branch by looking at the Changelog: [https://github.com/celery/celery/blob/master/Changelog](https://github.com/celery/celery/blob/master/Changelog)

If the branch is in active development the topmost version info should contain meta-data like:

```
4.3.0
======
:release-date: TBA
:status: DEVELOPMENT
:branch: dev (git calls this master)
```

The status field can be one of:

- **PLANNING**
  
  The branch is currently experimental and in the planning stage.

- **DEVELOPMENT**
  
  The branch is in active development, but the test suite should be passing and the product should be working and possible for users to test.

- **FROZEN**
  
  The branch is frozen, and no more features will be accepted. When a branch is frozen the focus is on testing the version as much as possible before it is released.

**dev branch**

The dev branch (called “master” by git), is where development of the next version happens.
Maintenance branches

Maintenance branches are named after the version – for example, the maintenance branch for the 2.2.x series is named 2.2.

Previously these were named releaseXX-maint.

The versions we currently maintain is:

- 4.2
  This is the current series.
- 4.1
  Drop support for python 2.6. Add support for python 3.4, 3.5 and 3.6.
- 3.1
  Official support for python 2.6, 2.7 and 3.3, and also supported on PyPy.

Archived branches

Archived branches are kept for preserving history only, and theoretically someone could provide patches for these if they depend on a series that’s no longer officially supported.

An archived version is named X.Y-archived.

To maintain a cleaner history and drop compatibility to continue improving the project, we do not have any archived version right now.

Feature branches

Major new features are worked on in dedicated branches. There’s no strict naming requirement for these branches.

Feature branches are removed once they’ve been merged into a release branch.

3.5.6 Tags

- Tags are used exclusively for tagging releases. A release tag is named with the format vX.Y.Z – for example v2.3.1.
- Experimental releases contain an additional identifier vX.Y.Z-id – for example v3.0.0-rc1.
- Experimental tags may be removed after the official release.

3.5.7 Working on Features & Patches

Note: Contributing to Celery should be as simple as possible, so none of these steps should be considered mandatory.

You can even send in patches by email if that’s your preferred work method. We won’t like you any less, any contribution you make is always appreciated!

However, following these steps may make maintainer’s life easier, and may mean that your changes will be accepted sooner.
Forking and setting up the repository

First you need to fork the Celery repository, a good introduction to this is in the GitHub Guide: Fork a Repo.

After you have cloned the repository, you should checkout your copy to a directory on your machine:

```
git clone git@github.com:username/celery.git
```

When the repository is cloned, enter the directory to set up easy access to upstream changes:

```
cd celery
git remote add upstream git://github.com/celery/celery.git
git fetch upstream
```

If you need to pull in new changes from upstream you should always use the `--rebase` option to `git pull`:

```
git pull --rebase upstream master
```

With this option, you don’t clutter the history with merging commit notes. See Rebasing merge commits in git. If you want to learn more about rebasing, see the Rebase section in the GitHub guides.

If you need to work on a different branch than the one git calls `master`, you can fetch and checkout a remote branch like this:

```
git checkout --track -b 5.0-devel upstream/5.0-devel
```

**Note:** Any feature or fix branch should be created from `upstream/master`.

Developing and Testing with Docker

Because of the many components of Celery, such as a broker and backend, Docker and docker-compose can be utilized to greatly simplify the development and testing cycle. The Docker configuration here requires a Docker version of at least 17.13.0 and `docker-compose` 1.13.0+.

The Docker components can be found within the `docker/` folder and the Docker image can be built via:

```
$ docker-compose build celery
```

and run via:

```
$ docker-compose run --rm celery <command>
```

where `<command>` is a command to execute in a Docker container. The `--rm` flag indicates that the container should be removed after it is exited and is useful to prevent accumulation of unwanted containers.

Some useful commands to run:

- `bash`

  To enter the Docker container like a normal shell

- `make test`

  To run the test suite. **Note:** This will run tests using python 3.8 by default.

- `tox`

  To run tox and test against a variety of configurations. **Note:** This command will run tests for every environment defined in `tox.ini`. It takes a while.

- `pyenv exec python{2.7,3.5,3.6,3.7,3.8} -m pytest t/unit`
To run unit tests using `pytest`:

**Note:** `{2.7,3.5,3.6,3.7,3.8}` means you can use any of those options. e.g. `pyenv exec python3.6 -m pytest t/unit`

- `pyenv exec python{2.7,3.5,3.6,3.7,3.8} -m pytest t/integration`

To run integration tests using `pytest`:

**Note:** `{2.7,3.5,3.6,3.7,3.8}` means you can use any of those options. e.g. `pyenv exec python3.6 -m pytest t/unit`

By default, `docker-compose` will mount the Celery and test folders in the Docker container, allowing code changes and testing to be immediately visible inside the Docker container. Environment variables, such as the broker and backend to use are also defined in the `docker/docker-compose.yml` file.

By running `docker-compose build celery` an image will be created with the name `celery/celery:dev`. This docker image has every dependency needed for development installed. `pyenv` is used to install multiple python versions, the docker image offers python 2.7, 3.5, 3.6, 3.7 and 3.8. The default python version is set to 3.8.

The `docker-compose.yml` file defines the necessary environment variables to run integration tests. The `celery` service also mounts the codebase and sets the `PYTHONPATH` environment variable to `/home/developer/celery`. By setting `PYTHONPATH` the service allows to use the mounted codebase as global module for development. If you prefer, you can also run `python -m pip install -e .` to install the codebase in development mode.

If you would like to run a Django or stand alone project to manually test or debug a feature, you can use the image built by `docker-compose` and mount your custom code. Here’s an example:

Assuming a folder structure such as:

```
+ celery_project
  + celery # repository cloned here.
  + my_project
    - manage.py
  + my_project
    - views.py
```

In the previous example, we are using the image that we can build from this repository and mounting the celery code base as well as our custom project.
Running the unit test suite

If you like to develop using virtual environments or just outside docker, you must make sure all necessary dependencies are installed. There are multiple requirements files to make it easier to install all dependencies. You do not have to use every requirements file but you must use `default.txt`.

```
# pip install -U -r requirements/default.txt
```

To run the Celery test suite you need to install `requirements/test.txt`.

```
$ pip install -U -r requirements/test.txt
$ pip install -U -r requirements/default.txt
```

After installing the dependencies required, you can now execute the test suite by calling `py.test`:

```
$ py.test t/unit
$ py.test t/integration
```

Some useful options to `py.test` are:

- `-x`
  Stop running the tests at the first test that fails.
- `-s`
  Don’t capture output
- `-v`
  Run with verbose output.

If you want to run the tests for a single test file only you can do so like this:

```
$ py.test t/unit/worker/test_worker.py
```

Calculating test coverage

To calculate test coverage you must first install the `pytest-cov` module.

Installing the `pytest-cov` module:

```
$ pip install -U pytest-cov
```

Code coverage in HTML format

1. Run `py.test` with the `--cov-report=html` argument enabled:

```
$ py.test --cov=celery --cov-report=html
```

2. The coverage output will then be located in the `htmlcov/` directory:

```
$ open htmlcov/index.html
```
Code coverage in XML (Cobertura-style)

1. Run `py.test` with the `--cov-report=xml` argument enabled:

```
$ py.test --cov=celery --cov-report=xml
```

1. The coverage XML output will then be located in the `coverage.xml` file.

Running the tests on all supported Python versions

There’s a tox configuration file in the top directory of the distribution.
To run the tests for all supported Python versions simply execute:

```
$ tox
```

Use the `tox -e` option if you only want to test specific Python versions:

```
$ tox -e 2.7
```

Building the documentation

To build the documentation, you need to install the dependencies listed in `requirements/docs.txt` and `requirements/default.txt`:

```
$ pip install -U -r requirements/docs.txt
$ pip install -U -r requirements/default.txt
```

Additionally, to build with no warnings, you will need to install the following packages:

```
$ apt-get install texlive texlive-latex-extra dvipng
```

After these dependencies are installed, you should be able to build the docs by running:

```
$ cd docs
$ rm -rf _build
$ make html
```

Make sure there are no errors or warnings in the build output. After building succeeds, the documentation is available at `_build/html`.

Verifying your contribution

To use these tools, you need to install a few dependencies. These dependencies can be found in `requirements/pkgutils.txt`.

Installing the dependencies:

```
$ pip install -U -r requirements/pkgutils.txt
```
pyflakes & PEP-8

To ensure that your changes conform to PEP 8 and to run pyflakes execute:

```
$ make flakecheck
```

To not return a negative exit code when this command fails, use the `flakes` target instead:

```
$ make flakes
```

API reference

To make sure that all modules have a corresponding section in the API reference, please execute:

```
$ make apicheck
```

If files are missing, you can add them by copying an existing reference file.

If the module is internal, it should be part of the internal reference located in `docs/internals/reference/`. If the module is public, it should be located in `docs/reference/`.

For example, if reference is missing for the module `celery.worker.awesome` and this module is considered part of the public API, use the following steps:

Use an existing file as a template:

```
$ cd docs/reference/
$ cp celery.schedules.rst celery.worker.awesome.rst
```

Edit the file using your favorite editor:

```
$ vim celery.worker.awesome.rst
```

```
# change every occurrence of `celery.schedules` to
# `celery.worker.awesome`
```

Edit the index using your favorite editor:

```
$ vim index.rst
```

```
# Add `celery.worker.awesome` to the index.
```

Commit your changes:

```
# Add the file to git
$ git add celery.worker.awesome.rst
$ git add index.rst
$ git commit celery.worker.awesome.rst index.rst \ 
   -m "Adds reference for celery.worker.awesome"
```

Isort

Isort is a python utility to help sort imports alphabetically and separated into sections. The Celery project uses isort to better maintain imports on every module. Please run isort if there are any new modules or the imports on an existent module had to be modified.

3.5. Contributing
Creating pull requests

When your feature/bugfix is complete, you may want to submit a pull request, so that it can be reviewed by the maintainers.

Before submitting a pull request, please make sure you go through this checklist to make it easier for the maintainers to accept your proposed changes:

- [ ] Make sure any change or new feature has a unit and/or integration test. If a test is not written, a label will be assigned to your PR with the name Needs Test Coverage.

- [ ] Make sure unit test coverage does not decrease. `py.test -xv --cov=celery --cov-report=xml --cov-report term` You can check the current test coverage here: https://codecov.io/gh/celery/celery

- [ ] Run `flake8` against the code. The following commands are valid and equivalent.:

```
$ flake8 --j 2 celery/ t/
$ make flakecheck
$ tox -e flake8
```

- [ ] Run `flakeplus` against the code. The following commands are valid and equivalent.:

```
$ flakeplus --2.7 celery/ t/
$ make flakes
$ tox -e flakeplus
```

- [ ] Run `pydocstyle` against the code. The following commands are valid and equivalent.:

```
$ pydocstyle celery/
$ tox -e pydocstyle
```

- [ ] Build api docs to make sure everything is OK. The following commands are valid and equivalent.:

```
$ make apicheck
$ cd docs && sphinx-build -b apicheck -d _build/doctrees . _build/apicheck
$ tox -e apicheck
```

- [ ] Build configcheck. The following commands are valid and equivalent.:

```
$ make configcheck
$ cd docs && sphinx-build -b configcheck -d _build/doctrees . _build/ --configcheck
$ tox -e configcheck
```

- [ ] Run `bandit` to make sure there’s no security issues. The following commands are valid and equivalent.:

```
$ pip install -U bandit
$ bandit -b bandit.json celery/
$ tox -e bandit
```
• Run unit and integration tests for every python version. The following commands are valid and equivalent:

$ tox -v

• Confirm isort on any new or modified imports:

$ isort my_module.py --diff

Creating pull requests is easy, and they also let you track the progress of your contribution. Read the Pull Requests section in the GitHub Guide to learn how this is done.

You can also attach pull requests to existing issues by following the steps outlined here: https://bit.ly/koJoso

You can also use hub to create pull requests. Example: https://theiconic.tech/git-hub-fbe2e13ef4d1

Status Labels

There are different labels used to easily manage github issues and PRs. Most of these labels make it easy to categorize each issue with important details. For instance, you might see a Component:canvas label on an issue or PR. The Component:canvas label means the issue or PR corresponds to the canvas functionality. These labels are set by the maintainers and for the most part external contributors should not worry about them. A subset of these labels are prepended with Status:. Usually the Status: labels show important actions which the issue or PR needs. Here is a summary of such statuses:

• Status: Cannot Reproduce
  One or more Celery core team member has not been able to reproduce the issue.

• Status: Confirmed
  The issue or PR has been confirmed by one or more Celery core team member.

• Status: Duplicate
  A duplicate issue or PR.

• Status: Feedback Needed
  One or more Celery core team member has asked for feedback on the issue or PR.

• Status: Has Testcase
  It has been confirmed the issue or PR includes a test case. This is particularly important to correctly write tests for any new feature or bug fix.

• Status: In Progress
  The PR is still in progress.

• Status: Invalid
  The issue reported or the PR is not valid for the project.

• Status: Needs Documentation
  The PR does not contain documentation for the feature or bug fix proposed.

• Status: Needs Rebase
  The PR has not been rebased with master. It is very important to rebase PRs before they can be merged to master to solve any merge conflicts.
• **Status: Needs Test Coverage**

Celery uses codecov to verify code coverage. Please make sure PRs do not decrease code coverage. This label will identify PRs which need code coverage.

• **Status: Needs Test Case**

The issue or PR needs a test case. A test case can be a minimal code snippet that reproduces an issue or a detailed set of instructions and configuration values that reproduces the issue reported. If possible a test case can be submitted in the form of a PR to Celery’s integration suite. The test case will be marked as failed until the bug is fixed. When a test case cannot be run by Celery’s integration suite, then it’s better to describe in the issue itself.

• **Status: Needs Verification**

This label is used to notify other users we need to verify the test case offered by the reporter and/or we need to include the test in our integration suite.

• **Status: Not a Bug**

It has been decided the issue reported is not a bug.

• **Status: Won’t Fix**

It has been decided the issue will not be fixed. Sadly the Celery project does not have unlimited resources and sometimes this decision has to be made. Although, any external contributors are invited to help out even if an issue or PR is labeled as **Status: Won’t Fix**.

• **Status: Works For Me**

One or more Celery core team members have confirmed the issue reported works for them.

### 3.5.8 Coding Style

You should probably be able to pick up the coding style from surrounding code, but it is a good idea to be aware of the following conventions.

- All Python code must follow the PEP 8 guidelines.

```
pep8 is a utility you can use to verify that your code is following the conventions.
```

- Docstrings must follow the PEP 257 conventions, and use the following style.

Do this:

```python
def method(self, arg):
    """Short description.
    More details.
    """
```

or:

```python
def method(self, arg):
    """Short description.""
```

but not this:
def method(self, arg):
    """
    Short description.
    """

- Lines shouldn’t exceed 78 columns.

You can enforce this in **vim** by setting the `textwidth` option:

```
set textwidth=78
```

If adhering to this limit makes the code less readable, you have one more character to go on. This means 78 is a soft limit, and 79 is the hard limit :) 

- Import order
  - Python standard library (`import xxx`)
  - Python standard library (`from xxx import`)
  - Third-party packages.
  - Other modules from the current package.

or in case of code using Django:
  - Python standard library (`import xxx`)
  - Python standard library (`from xxx import`)
  - Third-party packages.
  - Django packages.
  - Other modules from the current package.

Within these sections the imports should be sorted by module name.

Example:

```
import threading
import time

from collections import deque
from Queue import Queue, Empty

from .platforms import Pidfile
from .five import zip_longest, items, range
from .utils.time import maybe_timedelta
```

- Wild-card imports must not be used (`from xxx import *`).
- For distributions where Python 2.5 is the oldest support version, additional rules apply:
  - Absolute imports must be enabled at the top of every module:
    ```python
    from __future__ import absolute_import
    ```
  - If the module uses the `with` statement and must be compatible with Python 2.5 (celery isn’t), then it must also enable that:
    ```python
    from __future__ import with_statement
    ```
---

Every future import must be on its own line, as older Python 2.5 releases didn’t support importing multiple features on the same future import line:

```python
# Good
from __future__ import absolute_import
from __future__ import with_statement

# Bad
from __future__ import absolute_import, with_statement
```

(Note that this rule doesn’t apply if the package doesn’t include support for Python 2.5)

- Note that we use “new-style” relative imports when the distribution doesn’t support Python versions below 2.5

This requires Python 2.5 or later:

```python
from . import submodule
```

### 3.5.9 Contributing features requiring additional libraries

Some features like a new result backend may require additional libraries that the user must install.

We use setuptools `extra_requires` for this, and all new optional features that require third-party libraries must be added.

1) Add a new requirements file in `requirements/extras`

   For the Cassandra backend this is `requirements/extras/cassandra.txt`, and the file looks like this:

   ```plaintext
   pycassa
   ```

   These are pip requirement files, so you can have version specifiers and multiple packages are separated by newline. A more complex example could be:

   ```plaintext
   # pycassa 2.0 breaks Foo
   pycassa>=1.0,<2.0
   thrift
   ```

2) Modify `setup.py`

   After the requirements file is added, you need to add it as an option to `setup.py` in the `extras_require` section:

   ```python
   extra['extras_require'] = {
       # ...
       'cassandra': extras('cassandra.txt'),
   }
   ```

3) Document the new feature in `docs/includes/installation.txt`

   You must add your feature to the list in the `Bundles` section of `docs/includes/installation.txt`.

   After you’ve made changes to this file, you need to render the distro README file:

   ```bash
   $ pip install -U requirements/pkgutils.txt
   $ make readme
   ```
---
That’s all that needs to be done, but remember that if your feature adds additional configuration options, then these needs to be documented in docs/configuration.rst. Also, all settings need to be added to the celery/app/defaults.py module.

Result backends require a separate section in the docs/configuration.rst file.

### 3.5.10 Contacts

This is a list of people that can be contacted for questions regarding the official git repositories, PyPI packages Read the Docs pages.

If the issue isn’t an emergency then it’s better to [report an issue](#).

3.5.12 Release Procedure

Updating the version number

The version number must be updated in three places:

- celery/__init__.py
- docs/include/introduction.txt
- README.rst

The changes to the previous files can be handled with the [\texttt{bumpversion} command line tool] (https://pypi.org/project/bumpversion/). The corresponding configuration lives in .bumpversion.cfg. To do the necessary changes, run:

\begin{verbatim}
$ bumpversion
\end{verbatim}

After you have changed these files, you must render the README files. There’s a script to convert sphinx syntax to generic reStructured Text syntax, and the make target \texttt{readme} does this for you:

\begin{verbatim}
$ make readme
\end{verbatim}

Now commit the changes:

\begin{verbatim}
$ git commit -a -m "Bumps version to X.Y.Z"
\end{verbatim}

and make a new version tag:

\begin{verbatim}
$ git tag vX.Y.Z
$ git push --tags
\end{verbatim}
### Releasing

Commands to make a new public stable release:

```bash
$ make distcheck  # checks pep8, autodoc index, runs tests and more
$ make dist     # NOTE: Runs git clean -xdf and removes files not in the repo.
$ python setup.py sdist upload --sign --identity='Celery Security Team'
$ python setup.py bdist_wheel upload --sign --identity='Celery Security Team'
```

If this is a new release series then you also need to do the following:

- **Go to the Read The Docs management interface at:**  https://readthedocs.org/projects/celery/?fromdocs=celery
  - Enter “Edit project”
    - Change default branch to the branch of this series, for example, use the 2.4 branch for the 2.4 series.
  - Also add the previous version under the “versions” tab.

### 3.6 Community Resources

This is a list of external blog posts, tutorials, and slides related to Celery. If you have a link that’s missing from this list, please contact the mailing-list or submit a patch.

3.7.1 Task Cookbook

- **Ensuring a task is only executed one at a time**

## Ensuring a task is only executed one at a time

You can accomplish this by using a lock.

In this example we’ll be using the cache framework to set a lock that’s accessible for all workers.

It’s part of an imaginary RSS feed importer called *djangofeeds*. The task takes a feed URL as a single argument, and imports that feed into a Django model called *Feed*. We ensure that it’s not possible for two or more workers to import the same feed at the same time by setting a cache key consisting of the MD5 check-sum of the feed URL.

The cache key expires after some time in case something unexpected happens, and something always will…

For this reason your tasks run-time shouldn’t exceed the timeout.

**Note:** In order for this to work correctly you need to be using a cache backend where the `.add` operation is atomic. *memcached* is known to work well for this purpose.

```python
from celery import task
from celery.five import monotonic
from celery.utils.log import get_task_logger
from contextlib import contextmanager
from django.core.cache import cache
from hashlib import md5
from djangofeeds.models import Feed

logger = get_task_logger(__name__)

LOCK_EXPIRE = 60 * 10  # Lock expires in 10 minutes

@contextmanager
def memcache_lock(lock_id, oid):
    ...
```

(continues on next page)
timeout_at = monotonic() + LOCK_EXPIRE - 3
# cache.add fails if the key already exists
status = cache.add(lock_id, oid, LOCK_EXPIRE)
try:
    yield status
finally:
    # memcache delete is very slow, but we have to use it to take
    # advantage of using add() for atomic locking
    if monotonic() < timeout_at and status:
        # don't release the lock if we exceeded the timeout
        # to lessen the chance of releasing an expired lock
        # owned by someone else
        # also don't release the lock if we didn't acquire it
        cache.delete(lock_id)

@task(bind=True)
def import_feed(self, feed_url):
    # The cache key consists of the task name and the MD5 digest
    # of the feed URL.
    feed_url_hexdigest = md5(feed_url).hexdigest()
    lock_id = '{0}-lock-{1}'.format(self.name, feed_url_hexdigest)
    logger.debug('Importing feed: %s', feed_url)
    with memcache_lock(lock_id, self.app.oid) as acquired:
        if acquired:
            return Feed.objects.import_feed(feed_url).url
    logger.debug('Feed %s is already being imported by another worker', feed_url)

3.8 Frequently Asked Questions

- **General**
  - What kinds of things should I use Celery for?
- **Misconceptions**
  - Does Celery really consist of 50.000 lines of code?
  - Does Celery have many dependencies?
    - * celery
    - * kombu
  - Is Celery heavy-weight?
  - Is Celery dependent on pickle?
  - Is Celery for Django only?
  - Do I have to use AMQP/RabbitMQ?
  - Is Celery multilingual?
- **Troubleshooting**
  - MySQL is throwing deadlock errors, what can I do?
- The worker isn’t doing anything, just hanging
- Task results aren’t reliably returning
- Why is Task.delay/apply*/the worker just hanging?
- Does it work on FreeBSD?
- I’m having IntegrityError: Duplicate Key errors. Why?
- Why aren’t my tasks processed?
- Why won’t my Task run?
- Why won’t my periodic task run?
- How do I purge all waiting tasks?
- I’ve purged messages, but there are still messages left in the queue?

- Results
  - How do I get the result of a task if I have the ID that points there?

- Security
  - Isn’t using pickle a security concern?
  - Can messages be encrypted?
  - Is it safe to run celery worker as root?

- Brokers
  - Why is RabbitMQ crashing?
  - Can I use Celery with ActiveMQ/STOMP?
  - What features aren’t supported when not using an AMQP broker?

- Tasks
  - How can I reuse the same connection when calling tasks?
  - sudo in a subprocess returns None
  - Why do workers delete tasks from the queue if they’re unable to process them?
  - Can I call a task by name?
  - Can I get the task id of the current task?
  - Can I specify a custom task_id?
  - Can I use decorators with tasks?
  - Can I use natural task ids?
  - Can I run a task once another task has finished?
  - Can I cancel the execution of a task?
  - Why aren’t my remote control commands received by all workers?
  - Can I send some tasks to only some servers?
  - Can I disable prefetching of tasks?
  - Can I change the interval of a periodic task at runtime?
3.8.1 General

What kinds of things should I use Celery for?

Answer: Queue everything and delight everyone is a good article describing why you’d use a queue in a web context. These are some common use cases:

- Running something in the background. For example, to finish the web request as soon as possible, then update the users page incrementally. This gives the user the impression of good performance and “snappiness”, even though the real work might actually take some time.
- Running something after the web request has finished.
- Making sure something is done, by executing it asynchronously and using retries.
- Scheduling periodic work.

And to some degree:
- Distributed computing.
- Parallel execution.

3.8.2 Misconceptions

Does Celery really consist of 50.000 lines of code?

Answer: No, this and similarly large numbers have been reported at various locations.

The numbers as of this writing are:

- core: 7,141 lines of code.
- tests: 14,209 lines.
- backends, contrib, compat utilities: 9,032 lines.

Lines of code isn’t a useful metric, so even if Celery did consist of 50k lines of code you wouldn’t be able to draw any conclusions from such a number.
**Does Celery have many dependencies?**

A common criticism is that Celery uses too many dependencies. The rationale behind such a fear is hard to imagine, especially considering code reuse as the established way to combat complexity in modern software development, and that the cost of adding dependencies is very low now that package managers like pip and PyPI makes the hassle of installing and maintaining dependencies a thing of the past.

Celery has replaced several dependencies along the way, and the current list of dependencies are:

**celery**

- **kombu**
  
  Kombu is part of the Celery ecosystem and is the library used to send and receive messages. It’s also the library that enables us to support many different message brokers. It’s also used by the OpenStack project, and many others, validating the choice to separate it from the Celery code-base.

- **billiard**
  
  Billiard is a fork of the Python multiprocessing module containing many performance and stability improvements. It’s an eventual goal that these improvements will be merged back into Python one day.

  It’s also used for compatibility with older Python versions that don’t come with the multiprocessing module.

- **pytz**
  
  The pytz module provides timezone definitions and related tools.

**kombu**

Kombu depends on the following packages:

- **amqp**
  
  The underlying pure-Python amqp client implementation. AMQP being the default broker this is a natural dependency.

---

**Note:** To handle the dependencies for popular configuration choices Celery defines a number of “bundle” packages, see Bundles.

---

**Is Celery heavy-weight?**

Celery poses very little overhead both in memory footprint and performance.

But please note that the default configuration isn’t optimized for time nor space, see the Optimizing guide for more information.

**Is Celery dependent on pickle?**

**Answer:** No, Celery can support any serialization scheme.

We have built-in support for JSON, YAML, Pickle, and msgpack. Every task is associated with a content type, so you can even send one task using pickle, another using JSON.

The default serialization support used to be pickle, but since 4.0 the default is now JSON. If you require sending complex Python objects as task arguments, you can use pickle as the serialization format, but see notes in Serializers.
If you need to communicate with other languages you should use a serialization format suited to that task, which pretty much means any serializer that’s not pickle.

You can set a global default serializer, the default serializer for a particular Task, or even what serializer to use when sending a single task instance.

**Is Celery for Django only?**

**Answer:** No, you can use Celery with any framework, web or otherwise.

**Do I have to use AMQP/RabbitMQ?**

**Answer:** No, although using RabbitMQ is recommended you can also use Redis, SQS, or Qpid. See *Brokers* for more information.

Redis as a broker won’t perform as well as an AMQP broker, but the combination RabbitMQ as broker and Redis as a result store is commonly used. If you have strict reliability requirements you’re encouraged to use RabbitMQ or another AMQP broker. Some transports also use polling, so they’re likely to consume more resources. However, if you for some reason aren’t able to use AMQP, feel free to use these alternatives. They will probably work fine for most use cases, and note that the above points are not specific to Celery; If using Redis/database as a queue worked fine for you before, it probably will now. You can always upgrade later if you need to.

**Is Celery multilingual?**

**Answer:** Yes.

*worker* is an implementation of Celery in Python. If the language has an AMQP client, there shouldn’t be much work to create a worker in your language. A Celery worker is just a program connecting to the broker to process messages.

Also, there’s another way to be language-independent, and that’s to use REST tasks, instead of your tasks being functions, they’re URLs. With this information you can even create simple web servers that enable preloading of code. Simply expose an endpoint that performs an operation, and create a task that just performs an HTTP request to that endpoint.

You can also use *Flower’s REST API* to invoke tasks.

### 3.8.3 Troubleshooting

**MySQL is throwing deadlock errors, what can I do?**

**Answer:** MySQL has default isolation level set to *REPEATABLE-READ*, if you don’t really need that, set it to *READ-COMMITTED*. You can do that by adding the following to your *my.cnf*:

```
[mysqld]
transaction-isolation = READ-COMMITTED
```

For more information about InnoDB’s transaction model see *MySQL - The InnoDB Transaction Model and Locking* in the MySQL user manual.

(Thanks to Honza Kral and Anton Tsigularov for this solution)
The worker isn’t doing anything, just hanging

**Answer:** See *MySQL is throwing deadlock errors, what can I do?*, or *Why is Task.delay/apply*/the worker just hanging?.

Task results aren’t reliably returning

**Answer:** If you’re using the database backend for results, and in particular using MySQL, see *MySQL is throwing deadlock errors, what can I do?*.

Why is Task.delay/apply*/the worker just hanging?

**Answer:** There’s a bug in some AMQP clients that’ll make it hang if it’s not able to authenticate the current user, the password doesn’t match or the user doesn’t have access to the virtual host specified. Be sure to check your broker logs (for RabbitMQ that’s `/var/log/rabbitmq/rabbit.log` on most systems), it usually contains a message describing the reason.

Does it work on FreeBSD?

**Answer:** Depends;

When using the RabbitMQ (AMQP) and Redis transports it should work out of the box.

For other transports the compatibility prefork pool is used and requires a working POSIX semaphore implementation, this is enabled in FreeBSD by default since FreeBSD 8.x. For older version of FreeBSD, you have to enable POSIX semaphores in the kernel and manually recompile billiard.

I’m having IntegrityError: Duplicate Key errors. Why?

**Answer:** See *MySQL is throwing deadlock errors, what can I do?*. Thanks to @@howsthedotcom.

Why aren’t my tasks processed?

**Answer:** With RabbitMQ you can see how many consumers are currently receiving tasks by running the following command:

```
$ rabbitmqctl list_queues -p <myvhost> name messages consumers
Listing queues ...
celery 2891  2
```

This shows that there’s 2891 messages waiting to be processed in the task queue, and there are two consumers processing them.

One reason that the queue is never emptied could be that you have a stale worker process taking the messages hostage. This could happen if the worker wasn’t properly shut down.

When a message is received by a worker the broker waits for it to be acknowledged before marking the message as processed. The broker won’t re-send that message to another consumer until the consumer is shut down properly.

If you hit this problem you have to kill all workers manually and restart them:
$ pkill 'celery worker'
$ # - If you don't have pkill use:
$ # ps auxww | awk '/celery worker/ {print $2}' | xargs kill

You may have to wait a while until all workers have finished executing tasks. If it’s still hanging after a long time you can kill them by force with:

$ pkill -9 'celery worker'
$ # - If you don't have pkill use:
$ # ps auxww | awk '/celery worker/ {print $2}' | xargs kill -9

Why won’t my Task run?

**Answer:** There might be syntax errors preventing the tasks module being imported.
You can find out if Celery is able to run the task by executing the task manually:

```
>>> from myapp.tasks import MyPeriodicTask
>>> MyPeriodicTask.delay()
```

Watch the workers log file to see if it’s able to find the task, or if some other error is happening.

Why won’t my periodic task run?

**Answer:** See Why won’t my Task run?.

How do I purge all waiting tasks?

**Answer:** You can use the `celery purge` command to purge all configured task queues:

```
$ celery -A proj purge
```

or programmatically:

```
>>> from proj.celery import app
>>> app.control.purge()
1753
```

If you only want to purge messages from a specific queue you have to use the AMQP API or the `celery amqp` utility:

```
$ celery -A proj amqp queue.purge <queue name>
```

The number 1753 is the number of messages deleted.

You can also start the worker with the `--purge` option enabled to purge messages when the worker starts.

I’ve purged messages, but there are still messages left in the queue?

**Answer:** Tasks are acknowledged (removed from the queue) as soon as they’re actually executed. After the worker has received a task, it will take some time until it’s actually executed, especially if there are a lot of tasks already waiting for
execution. Messages that aren’t acknowledged are held on to by the worker until it closes the connection to the broker (AMQP server). When that connection is closed (e.g., because the worker was stopped) the tasks will be re-sent by the broker to the next available worker (or the same worker when it has been restarted), so to properly purge the queue of waiting tasks you have to stop all the workers, and then purge the tasks using `celery.control.purge()`.

### 3.8.4 Results

**How do I get the result of a task if I have the ID that points there?**

**Answer:** Use `task.AsyncResult`:

```python
>>> result = my_task.AsyncResult(task_id)
>>> result.get()
```

This will give you a `AsyncResult` instance using the tasks current result backend.

If you need to specify a custom result backend, or you want to use the current application’s default backend you can use `app.AsyncResult`:

```python
>>> result = app.AsyncResult(task_id)
>>> result.get()
```

### 3.8.5 Security

**Isn’t using `pickle` a security concern?**

**Answer:** Indeed, since Celery 4.0 the default serializer is now JSON to make sure people are choosing serializers consciously and aware of this concern.

It’s essential that you protect against unauthorized access to your broker, databases and other services transmitting pickled data.

Note that this isn’t just something you should be aware of with Celery, for example also Django uses pickle for its cache client.

For the task messages you can set the `task_serializer` setting to “json” or “yaml” instead of pickle.

Similarly for task results you can set `result_serializer`.

For more details of the formats used and the lookup order when checking what format to use for a task see `Serializers`.

**Can messages be encrypted?**

**Answer:** Some AMQP brokers supports using SSL (including RabbitMQ). You can enable this using the `broker_use_ssl` setting.

It’s also possible to add additional encryption and security to messages, if you have a need for this then you should contact the `Mailing list`.

**Is it safe to run `celery worker` as root?**

**Answer:** No!
We’re not currently aware of any security issues, but it would be incredibly naive to assume that they don’t exist, so running the Celery services (celery worker, celery beat, celeryev, etc) as an unprivileged user is recommended.

### 3.8.6 Brokers

#### Why is RabbitMQ crashing?

**Answer:** RabbitMQ will crash if it runs out of memory. This will be fixed in a future release of RabbitMQ. Please refer to the RabbitMQ FAQ: https://www.rabbitmq.com/faq.html#node-runs-out-of-memory

**Note:** This is no longer the case, RabbitMQ versions 2.0 and above includes a new persister, that’s tolerant to out of memory errors. RabbitMQ 2.1 or higher is recommended for Celery.

If you’re still running an older version of RabbitMQ and experience crashes, then please upgrade!

Misconfiguration of Celery can eventually lead to a crash on older version of RabbitMQ. Even if it doesn’t crash, this can still consume a lot of resources, so it’s important that you’re aware of the common pitfalls.

- Events.

Running worker with the `-E` option will send messages for events happening inside of the worker.

Events should only be enabled if you have an active monitor consuming them, or if you purge the event queue periodically.

- AMQP backend results.

When running with the AMQP result backend, every task result will be sent as a message. If you don’t collect these results, they will build up and RabbitMQ will eventually run out of memory.

This result backend is now deprecated so you shouldn’t be using it. Use either the RPC backend for rpc-style calls, or a persistent backend if you need multi-consumer access to results.

Results expire after 1 day by default. It may be a good idea to lower this value by configuring the `result_expires` setting.

If you don’t use the results for a task, make sure you set the `ignore_result` option:

```python
@app.task(ignore_result=True)
def mytask():
    pass

class MyTask(Task):
    ignore_result = True
```

#### Can I use Celery with ActiveMQ/STOMP?

**Answer:** No. It used to be supported by Carrot (our old messaging library) but isn’t currently supported in Kombu (our new messaging library).

#### What features aren’t supported when not using an AMQP broker?

This is an incomplete list of features not available when using the virtual transports:

- Remote control commands (supported only by Redis).
• Monitoring with events may not work in all virtual transports.
• **The header and fanout exchange types** (*fanout* is supported by Redis).

### 3.8.7 Tasks

**How can I reuse the same connection when calling tasks?**

**Answer:** See the `broker_pool_limit` setting. The connection pool is enabled by default since version 2.5.

**sudo in a subprocess returns None**

There’s a `sudo` configuration option that makes it illegal for process without a tty to run `sudo`:

```
[Defaults]
requiretty
```

If you have this configuration in your `/etc/sudoers` file then tasks won’t be able to call `sudo` when the worker is running as a daemon. If you want to enable that, then you need to remove the line from `/etc/sudoers`.

See: [Apache Sudo Commands](http://timelordz.com/wiki/Apache_Sudo_Commands)

**Why do workers delete tasks from the queue if they’re unable to process them?**

**Answer:**

The worker rejects unknown tasks, messages with encoding errors and messages that don’t contain the proper fields (as per the task message protocol).

If it didn’t reject them they could be redelivered again and again, causing a loop.

Recent versions of RabbitMQ has the ability to configure a dead-letter queue for exchange, so that rejected messages is moved there.

**Can I call a task by name?**

**Answer:** Yes, use `app.send_task()`.

You can also call a task by name, from any language, using an AMQP client:

```python
>>> app.send_task('tasks.add', args=[2, 2], kwargs={})
<AsyncResult: 373550e8-b9a0-4666-bc61-ace01fa4f91d>
```

To use `chain`, `chord` or `group` with tasks called by name, use the `Celery.signature()` method:

```python
>>> chain(...
        app.signature('tasks.add', args=[2, 2], kwargs={}),
        ...)
<AsyncResult: e9d52312-c161-46f0-9013-2713e6df812d>
```
Can I get the task id of the current task?

**Answer:** Yes, the current id and more is available in the task request:

```python
@app.task(bind=True)
def mytask(self):
    cache.set(self.request.id, "Running")
```

For more information see *Task Request.*

If you don’t have a reference to the task instance you can use `app.current_task`:

```python
>>> app.current_task.request.id
```

But note that this will be any task, be it one executed by the worker, or a task called directly by that task, or a task called eagerly.

To get the current task being worked on specifically, use `current_worker_task`:

```python
>>> app.current_worker_task.request.id
```

**Note:** Both `current_task`, and `current_worker_task` can be `None`.

Can I specify a custom `task_id`?

**Answer:** Yes, use the `task_id` argument to `Task.apply_async()`:

```python
>>> task.apply_async(args, kwargs, task_id='...')
```

Can I use decorators with tasks?

**Answer:** Yes, but please see note in the sidebar at *Basics.*

Can I use natural task ids?

**Answer:** Yes, but make sure it’s unique, as the behavior for two tasks existing with the same id is undefined.

The world will probably not explode, but they can definitely overwrite each others results.

Can I run a task once another task has finished?

**Answer:** Yes, you can safely launch a task inside a task.

A common pattern is to add callbacks to tasks:

```python
from celery.utils.log import get_task_logger

logger = get_task_logger(__name__)

@app.task
def add(x, y):
    return x + y
```
Can I cancel the execution of a task?

**Answer:** Yes, use `result.revoke()`:

```python
>>> result = add.apply_async(args=[2, 2], countdown=120)
>>> result.revoke()
```

or if you only have the task id:

```python
>>> from proj.celery import app
>>> app.control.revoke(task_id)
```

The latter also support passing a list of task-ids as argument.

Why aren’t my remote control commands received by all workers?

**Answer:** To receive broadcast remote control commands, every worker node creates a unique queue name, based on the nodename of the worker.

If you have more than one worker with the same host name, the control commands will be received in round-robin between them.

To work around this you can explicitly set the nodename for every worker using the `-n` argument to `worker`:

```bash
$ celery -A proj worker -n worker1@%h
$ celery -A proj worker -n worker2@%h
```

where `%h` expands into the current hostname.

Can I send some tasks to only some servers?

**Answer:** Yes, you can route tasks to one or more workers, using different message routing topologies, and a worker instance can bind to multiple queues.

See [Routing Tasks](#) for more information.

Can I disable prefetching of tasks?

**Answer:** Maybe! The AMQP term “prefetch” is confusing, as it’s only used to describe the task prefetching limit. There’s no actual prefetching involved.

Disabling the prefetch limits is possible, but that means the worker will consume as many tasks as it can, as fast as possible.
A discussion on prefetch limits, and configuration settings for a worker that only reserves one task at a time is found here: *Prefetch Limits*.

**Can I change the interval of a periodic task at runtime?**

**Answer:** Yes, you can use the Django database scheduler, or you can create a new schedule subclass and override `is_due()`:

```python
from celery.schedules import schedule

class my_schedule(schedule):
    def is_due(self, last_run_at):
        return run_now, next_time_to_check
```

**Does Celery support task priorities?**

**Answer:** Yes, RabbitMQ supports priorities since version 3.5.0, and the Redis transport emulates priority support.

You can also prioritize work by routing high priority tasks to different workers. In the real world this usually works better than per message priorities. You can use this in combination with rate limiting, and per message priorities to achieve a responsive system.

**Should I use retry or acks_late?**

**Answer:** Depends. It’s not necessarily one or the other, you may want to use both.

`Task.retry` is used to retry tasks, notably for expected errors that is catch-able with the `try` block. The AMQP transaction isn’t used for these errors: *if the task raises an exception it's still acknowledged!*

The `acks_late` setting would be used when you need the task to be executed again if the worker (for some reason) crashes mid-execution. It’s important to note that the worker isn’t known to crash, and if it does it’s usually an unrecoverable error that requires human intervention (bug in the worker, or task code).

In an ideal world you could safely retry any task that’s failed, but this is rarely the case. Imagine the following task:

```python
@apptask
def process_upload(filename, tmpfile):
    # Increment a file count stored in a database
    increment_file_counter()
    add_file_metadata_to_db(filename, tmpfile)
    copy_file_to_destination(filename, tmpfile)
```

If this crashed in the middle of copying the file to its destination the world would contain incomplete state. This isn’t a critical scenario of course, but you can probably imagine something far more sinister. So for ease of programming we have less reliability; It’s a good default, users who require it and know what they are doing can still enable `acks_late` (and in the future hopefully use manual acknowledgment).

In addition `Task.retry` has features not available in AMQP transactions: delay between retries, max retries, etc.

So use retry for Python errors, and if your task is idempotent combine that with `acks_late` if that level of reliability is required.
Can I schedule tasks to execute at a specific time?

**Answer:** Yes. You can use the `eta` argument of `Task.apply_async()`.
See also *Periodic Tasks*.

Can I safely shut down the worker?

**Answer:** Yes, use the `TERM` signal.

This will tell the worker to finish all currently executing jobs and shut down as soon as possible. No tasks should be lost even with experimental transports as long as the shutdown completes.

You should never stop `worker` with the `KILL` signal (`kill -9`), unless you’ve tried `TERM` a few times and waited a few minutes to let it get a chance to shut down.

Also make sure you kill the main worker process only, not any of its child processes. You can direct a kill signal to a specific child process if you know the process is currently executing a task the worker shutdown is depending on, but this also means that a `WorkerLostError` state will be set for the task so the task won’t run again.

Identifying the type of process is easier if you have installed the `setproctitle` module:

```
$ pip install setproctitle
```

With this library installed you’ll be able to see the type of process in `ps` listings, but the worker must be restarted for this to take effect.

See also: *Stopping the worker*

Can I run the worker in the background on [platform]?

**Answer:** Yes, please see *Daemonization*.

### 3.8.8 Django

**What purpose does the database tables created by `django-celery-beat` have?**

When the database-backed schedule is used the periodic task schedule is taken from the `PeriodicTask` model, there are also several other helper tables (`IntervalSchedule`, `CrontabSchedule`, `PeriodicTasks`).

**What purpose does the database tables created by `django-celery-results` have?**

The Django database result backend extension requires two extra models: `TaskResult` and `GroupResult`.

### 3.8.9 Windows

**Does Celery support Windows?**

**Answer:** No.

Since Celery 4.x, Windows is no longer supported due to lack of resources.

But it may still work and we are happy to accept patches.
3.9 Change history

This document contains change notes for bugfix & new features in the 4.x series, please see *What's new in Celery 4.4 (Cliffs)* for an overview of what’s new in Celery 4.4.

3.9.1 4.4.0

release-date 2019-12-16 9.45 A.M UTC+6:00
release-by Asif Saif Uddin

• This version is officially supported on CPython 2.7, 3.5, 3.6, 3.7 & 3.8 and is also supported on PyPy2 & PyPy3. - Kombu 4.6.7

3.9.2 4.4.0rc5

release-date 2019-12-07 21.05 A.M UTC+6:00
release-by Asif Saif Uddin

• Kombu 4.6.7
• Events bootstrap disabled if no events (#5807)
• SQS - Reject on failure (#5843)
• Add a concurrency model with ThreadPoolExecutor (#5099)
• Add auto expiry for DynamoDB backend (#5805)
• Store extending result in all backends (#5661)
• Fix a race condition when publishing a very large chord header (#5850)
• Improve docs and test matrix

3.9.3 4.4.0rc4

release-date 2019-11-11 00.45 A.M UTC+6:00
release-by Asif Saif Uddin

• Kombu 4.6.6
• Py-AMQP 2.5.2
• Python 3.8
• Numerous bug fixes
• PyPy 7.2

3.9.4 4.4.0rc3

release-date 2019-08-14 23.00 P.M UTC+6:00
release-by Asif Saif Uddin

• Kombu 4.6.4
• Billiard 3.6.1
• Py-AMQP 2.5.1
• Avoid serializing datetime (#5606)
• Fix: (group()) | group()) not equals single group (#5574)
• Revert “Broker connection uses the heartbeat setting from app config.
• Additional file descriptor safety checks.
• fixed call for null args (#5631)
• Added generic path for cache backend.
• Fix Nested group(chain(group)) fails (#5638)
• Use self.run() when overriding __call__ (#5652)
• Fix termination of asyncloop (#5671)
• Fix migrate task to work with both v1 and v2 of the message protocol.
• Updating task_routes config during runtime now have effect.

3.9.5 4.4.0rc2

    release-date 2019-06-15 4:00 A.M UTC+6:00
    release-by Asif Saif Uddin
• Many bugs and regressions fixed.
• Kombu 4.6.3

3.9.6 4.4.0rc1

    release-date 2019-06-06 1:00 P.M UTC+6:00
    release-by Asif Saif Uddin
• Python 3.4 drop
• Kombu 4.6.1
• Replace deprecated PyMongo methods usage (#5443)
• Pass task request when calling update_state (#5474)
• Fix bug in remaining time calculation in case of DST time change (#5411)
• Fix missing task name when requesting extended result (#5439)
• Fix collections import issue on Python 2.7 (#5428)
• handle AttributeError in base backend exception deserializer (#5435)
• Make AsynPool’s proc_alive_timeout configurable (#5476)
• AMQP Support for extended result (#5495)
• Fix SQL Alchemy results backend to work with extended result (#5498)
• Fix restoring of exceptions with required param (#5500)
• Django: Re-raise exception if ImportError not caused by missing tasks module (#5211)
• Django: fixed a regression putting DB connections in invalid state when `CONN_MAX_AGE != 0` (#5515)
• Fixed `OSError` leading to lost connection to broker (#4457)
• Fixed an issue with inspect API unable get details of Request
• Fix mongodb backend authentication (#5527)
• Change column type for Extended Task Meta args/kwrgs to LargeBinary
• Handle `http_auth` in Elasticsearch backend results (#5545)
• Fix task serializer being ignored with `taskAlwaysEager=True` (#5549)
• Fix `task.replace` to work in `apply() as well as `apply_async()` (#5540)
• Fix sending of `worker_process_init` signal for solo worker (#5562)
• Fix exception message unpacking (#5565)
• Add delay parameter function to `beat_schedule` (#5558)
• Multiple documentation updates

3.9.7 4.3.0

release-date  2019-03-31 7:00 P.M UTC+3:00
release-by  Omer Katz
• Added support for broadcasting using a regular expression pattern or a glob pattern to multiple Pidboxes.  
  This allows you to inspect or ping multiple workers at once.
  Contributed by Dmitry Malinovsky & Jason Held
• Added support for PEP 420 namespace packages.
  This allows you to load tasks from namespace packages.
  Contributed by Colin Watson
• Added `acks_on_failure_or_timeout` as a setting instead of a task only option.
  This was missing from the original PR but now added for completeness.
  Contributed by Omer Katz
• Added the `task_received` signal.
  Contributed by Omer Katz
• Fixed a crash of our CLI that occurred for everyone using Python < 3.6.
  The crash was introduced in acd6025 by using the `ModuleNotFoundError` exception which was introduced
  in Python 3.6.
  Contributed by Omer Katz
• Fixed a crash that occurred when using the Redis result backend while the `result_expires` is set to None.
  Contributed by Toni Ruža & Omer Katz
• Added support the DNS seedlist connection format for the MongoDB result backend.
  This requires the `dnspython` package which will be installed by default when installing the dependencies for the
  MongoDB result backend.
  Contributed by George Psarakis
• Bump the minimum eventlet version to 0.24.1.
  Contributed by George Psarakis
• Replace the msgpack-python package with msgpack.
  We’re no longer using the deprecated package. See our important notes for this release for further details on how to upgrade.
  Contributed by Daniel Hahler
• Allow scheduling error handlers which are not registered tasks in the current worker.
  These kind of error handlers are now possible:

```python
from celery import Signature
Signature(
    'bar', args=['foo'],
    link_error=Signature('msg.err', queue='msg')
).apply_async()
```

• Additional fixes and enhancements to the SSL support of the Redis broker and result backend.
  Contributed by Jeremy Cohen

Code Cleanups, Test Coverage & CI Improvements by:

• Omer Katz
• Florian Chardin

Documentation Fixes by:

• Omer Katz
• Samuel Huang
• Amir Hossein Saeid Mehr
• Dmytro Litvinov

### 3.9.8 4.3.0 RC2

**release-date** 2019-03-03 9:30 P.M UTC+2:00

**release-by** Omer Katz

• **Filesystem Backend**: Added meaningful error messages for filesystem backend.
  Contributed by Lars Rinn

• **New Result Backend**: Added the ArangoDB backend.
  Contributed by Dilip Vamsi Moturi

• **Django**: Prepend current working directory instead of appending so that the project directory will have precedence over system modules as expected.
  Contributed by Antonin Delpeuch

• Bump minimum py-redis version to 3.2.0.
  Due to multiple bugs in earlier versions of py-redis that were causing issues for Celery, we were forced to bump the minimum required version to 3.2.0.
  Contributed by Omer Katz
- **Dependencies**: Bump minimum required version of Kombu to 4.4
  
  Contributed by Omer Katz

### 3.9.9 4.3.0 RC1

**release-date** 2019-02-20 5:00 PM IST

**release-by** Omer Katz

- **Canvas**: celery.chain.apply() does not ignore keyword arguments anymore when applying the chain.
  
  Contributed by Korijn van Golen

- **Result Set**: Don’t attempt to cache results in a celery.result.ResultSet.
  
  During a join, the results cache was populated using celery.result.ResultSet.get(), if one of the results contains an exception, joining unexpectedly failed.
  
  The results cache is now removed.
  
  Contributed by Derek Harland

- **Application**: celery.Celery.autodiscover_tasks() now attempts to import the package itself when the related_name keyword argument is None.
  
  Contributed by Alex Ioannidis

- **Windows Support**: On Windows 10, stale PID files prevented celery beat to run. We now remove them when a SystemExit is raised.
  
  Contributed by :github_user:`na387`

- **Task**: Added the new task_acks_on_failure_or_timeout setting.
  
  Acknowledging SQS messages on failure or timing out makes it impossible to use dead letter queues.
  
  We introduce the new option acks_on_failure_or_timeout, to ensure we can totally fallback on native SQS message lifecycle, using redeliveries for retries (in case of slow processing or failure) and transitions to dead letter queue after defined number of times.
  
  Contributed by Mario Kostelac

- **RabbitMQ Broker**: Adjust HA headers to work on RabbitMQ 3.x.
  
  This change also means we’re ending official support for RabbitMQ 2.x.
  
  Contributed by Asif Saif Uddin

- **Command Line**: Improve celery update error handling.
  
  Contributed by Federico Bond

- **Canvas**: Support chords with task_always_eager set to True.
  
  Contributed by Axel Haustant

- **Result Backend**: Optionally store task properties in result backend.
  
  Setting the result_extended configuration option to True enables storing additional task properties in the result backend.
  
  Contributed by John Arnold
• **Couchbase Result Backend**: Allow the Couchbase result backend to automatically detect the serialization format.
  Contributed by Douglas Rohde

• **New Result Backend**: Added the Azure Block Blob Storage result backend.
  The backend is implemented on top of the azure-storage library which uses Azure Blob Storage for a scalable low-cost PaaS backend.
  The backend was load tested via a simple nginx/gunicorn/sanic app hosted on a DS4 virtual machine (4 vCores, 16 GB RAM) and was able to handle 600+ concurrent users at ~170 RPS.
  The commit also contains a live end-to-end test to facilitate verification of the backend functionality. The test is activated by setting the `AZUREBLOCKBLOB_URL` environment variable to `azureblock-blob://{ConnectionString}` where the value for `ConnectionString` can be found in the Access Keys pane of a Storage Account resources in the Azure Portal.
  Contributed by Clemens Wolff

• **Task**: `celery.app.task.update_state()` now accepts keyword arguments.
  This allows passing extra fields to the result backend. These fields are unused by default but custom result backends can use them to determine how to store results.
  Contributed by Christopher Dignam

• **Gracefully handle consumer** `kombu.exceptions.DecodeError`.
  When using the v2 protocol the worker no longer crashes when the consumer encounters an error while decoding a message.
  Contributed by Steven Sklar

• **Deployment**: Fix init.d service stop.
  Contributed by Marcus McHale

• **Django**: Drop support for Django < 1.11.
  Contributed by Asif Saif Uddin

• **Django**: Remove old djcelery loader.
  Contributed by Asif Saif Uddin

• **Result Backend**: `celery.worker.request.Request` now passes `celery.app.task.Context` to the backend’s store_result functions.
  Since the class currently passes `self` to these functions, revoking a task resulted in corrupted task result data when django-celery-results was used.
  Contributed by Kiyohiro Yamaguchi

• **Worker**: Retry if the heartbeat connection dies.
  Previously, we keep trying to write to the broken connection. This results in a memory leak because the event dispatcher will keep appending the message to the outbound buffer.
  Contributed by Raf Geens

• **Celery Beat**: Handle microseconds when scheduling.
  Contributed by K Davis
• **Asynpool**: Fixed deadlock when closing socket.

Upon attempting to close a socket, `celery.concurrency.asynpool.AsynPool` only removed the queue writer from the hub but did not remove the reader. This led to a deadlock on the file descriptor and eventually the worker stopped accepting new tasks.

We now close both the reader and the writer file descriptors in a single loop iteration which prevents the deadlock.

Contributed by **Joshua Engelman**

• **Celery Beat**: Correctly consider timezone when calculating timestamp.

Contributed by :github_user:`yywing`

• **Celery Beat**: `celery.beat.Scheduler.schedules_equal()` can now handle either arguments being a `None` value.

Contributed by :github_user:`ratson`

• **Documentation/Sphinx**: Fixed Sphinx support for shared_task decorated functions.

Contributed by **Jon Banafato**

• **New Result Backend**: Added the CosmosDB result backend.

This change adds a new results backend. The backend is implemented on top of the pydocumentdb library which uses Azure CosmosDB for a scalable, globally replicated, high-performance, low-latency and high-throughput PaaS backend.

Contributed by **Clemens Wolff**

• **Application**: Added configuration options to allow separate multiple apps to run on a single RabbitMQ vhost.

The newly added `event_exchange` and `control_exchange` configuration options allow users to use separate Pidbox exchange and a separate events exchange.

This allow different Celery applications to run separately on the same vhost.

Contributed by **Artem Vasilyev**

• **Result Backend**: Forget parent result metadata when forgetting a result.

Contributed by :github_user:`tothegump`

• **Task Store** task arguments inside `celery.exceptions.MaxRetriesExceededError`.

Contributed by **Anthony Ruhier**

• **Result Backend**: Added the `result_accept_content` setting.

This feature allows to configure different accepted content for the result backend.

A special serializer (`auth`) is used for signed messaging, however the result_serializer remains in json, because we don’t want encrypted content in our result backend.

To accept unsigned content from the result backend, we introduced this new configuration option to specify the accepted content from the backend.

Contributed by **Benjamin Pereto**

• **Canvas**: Fixed error callback processing for class based tasks.

Contributed by **Victor Mireyev**

• **New Result Backend**: Added the S3 result backend.

Contributed by **Florian Chardin**
• **Task**: Added support for Cythonized Celery tasks.
  Contributed by Andrey Skabelin

• **Riak Result Backend**: Warn Riak backend users for possible Python 3.7 incompatibilities.
  Contributed by George Psarakis

• **Python Runtime**: Added Python 3.7 support.
  Contributed by Omer Katz & Asif Saif Uddin

• **Auth Serializer**: Revamped the auth serializer.
  The auth serializer received a complete overhaul. It was previously horribly broken.
  We now depend on cryptography instead of pyOpenSSL for this serializer.
  Contributed by Benjamin Pereto

• **Command Line**: celery report now reports kernel version along with other platform details.
  Contributed by Omer Katz

• **Canvas**: Fixed chords with chains which include sub chords in a group.
  Celery now correctly executes the last task in these types of canvases:

```python
import dummy.si

c = chord(
    group([
        chain(
            dummy.si(),
            chord(
                group([dummy.si(), dummy.si()]),
                dummy.si(),
            ),
        ),
        chain(
            dummy.si(),
            chord(
                group([dummy.si(), dummy.si()]),
                dummy.si(),
            ),
        ),
    ]),
    dummy.si()
)
c.delay().get()
```

Contributed by Maximilien Cuony

• **Canvas**: Complex canvases with error callbacks no longer raises an AttributeError.
  Very complex canvases such as this no longer raise an AttributeError which prevents constructing them.
  We do not know why this bug occurs yet.
  Contributed by Manuel Vázquez Acosta

• **Command Line**: Added proper error messages in cases where app cannot be loaded.
  Previously, celery crashed with an exception.
  We now print a proper error message.
• **Task**: Added the `task_default_priority` setting.

You can now set the default priority of a task using the `task_default_priority` setting. The setting’s value will be used if no priority is provided for a specific task.

Contributed by :github_user:`madprogrammer`

• **Dependencies**: Bump minimum required version of Kombu to 4.3 and Billiard to 3.6.

Contributed by Asif Saif Uddin

• **Result Backend**: Fix memory leak.

We reintroduced weak references to bound methods forAsyncResult callback promises, after adding full weakref support for Python 2 in vine. More details can be found in celery/celery#4839.

Contributed by George Psarakis and :github_user:`monsterxx03`.

• **Task Execution**: Fixed roundtrip serialization for eager tasks.

When doing the roundtrip serialization for eager tasks, the task serializer will always be JSON unless the `serializer` argument is present in the call to `celery.app.task.Task.apply_async()`. If the serializer argument is present but is ‘pickle’, an exception will be raised as pickle-serialized objects cannot be deserialized without specifying to `serialization.loads` what content types should be accepted. The Producer’s `serializer` seems to be set to `None`, causing the default to JSON serialization.

We now continue to use (in order) the `serializer` argument to `celery.app.task.Task.apply_async()`, if present, or the Producer’s serializer if not `None`. If the Producer’s serializer is `None`, it will use the Celery app’s `task_serializer` configuration entry as the serializer.

Contributed by Brett Jackson

• **Redis Result Backend**: The `celery.backends.redis.ResultConsumer` class no longer assumes `celery.backends.redis.ResultConsumer.start()` to be called before `celery.backends.redis.ResultConsumer.drain_events()`.

This fixes a race condition when using the Gevent workers pool.

Contributed by Noam Kush

• **Task**: Added the `task_inherit_parent_priority` setting.

Setting the `task_inherit_parent_priority` configuration option to `True` will make Celery tasks inherit the priority of the previous task linked to it.

Examples:

```
c = celery.chain(  
    add.s(2), # priority=None  
    add.s(3).set(priority=5), # priority=5  
    add.s(4), # priority=5  
    add.s(5).set(priority=3), # priority=3  
    add.s(6), # priority=3
    )
```

```
@app.task(bind=True)
def child_task(self):
    pass

@app.task(bind=True)
def parent_task(self):
    pass
```

(continues on next page)
child_task.delay()

# child_task will also have priority=5
parent_task.apply_async(args=[], priority=5)

Contributed by :github_user:`madprogrammer`

- **Canvas**: Added the `result_chord_join_timeout` setting.
  Previously, `celery.result.GroupResult.join()` had a fixed timeout of 3 seconds.
  The `result_chord_join_timeout` setting now allows you to change it.
  Contributed by :github_user:`srafehi`

3.9. Change history
3.10 What’s new in Celery 4.4 (Cliffs)

**Author** Asif Saif Uddin (auvipy at gmail.com)

### Change history

What’s new documents describe the changes in major versions, we also have a Change history that lists the changes in bugfix releases (0.0.x), while older series are archived under the History section.

Celery is a simple, flexible, and reliable distributed programming framework to process vast amounts of messages, while providing operations with the tools required to maintain a distributed system with python.

It’s a task queue with focus on real-time processing, while also supporting task scheduling.

Celery has a large and diverse community of users and contributors, you should come join us on IRC or our mailing-list.

To read more about Celery you should go read the introduction.

While this version is backward compatible with previous versions it’s important that you read the following section.

This version is officially supported on CPython 2.7, 3.5, 3.6, 3.7 & 3.8 and is also supported on PyPy2 & PyPy3.
3.10.1 Preface

The 4.4.0 release continues to improve our efforts to provide you with the best task execution platform for Python.

This release has been codenamed Cliffs which is one of my favorite tracks.

This release focuses on mostly bug fixes and usability improvement for developers. Many long standing bugs, usability issues, documentation issues & minor enhancement issues were squashed which improve the overall developers experience.

Celery 4.4 is the first release to support Python 3.8 & pypy36-7.2.

As we now begin to work on Celery 5, the next generation of our task execution platform, at least another 4.x is expected before Celery 5 stable release & will get support for at least 1 years depending on community demand and support.

We have also focused on reducing contribution friction and updated the contributing tools.

— Asif Saif Uddin
Wall of Contributors

Note: This wall was automatically generated from git history, so sadly it doesn’t not include the people who help with more important things like answering mailing-list questions.

3.10.2 Upgrading from Celery 4.3

Please read the important notes below as there are several breaking changes.

3.10.3 Important Notes

Supported Python Versions

The supported Python Versions are:

- CPython 2.7
- CPython 3.5
- CPython 3.6
- CPython 3.7
- CPython 3.8
- PyPy2.7 7.2 (pypy2)
- PyPy3.5 7.1 (pypy3)
- PyPy3.6 7.2 (pypy3)

Dropped support for Python 3.4

Celery now requires either Python 2.7 or Python 3.5 and above.

Python 3.4 has reached EOL in March 2019. In order to focus our efforts we have dropped support for Python 3.4 in this version.

If you still require to run Celery using Python 3.4 you can still use Celery 4.3. However we encourage you to upgrade to a supported Python version since no further security patches will be applied for Python 3.4.

Kombu

Starting from this release, the minimum required version is Kombu 4.6.6.

Billiard

Starting from this release, the minimum required version is Billiard 3.6.1.
Redis Message Broker

Due to multiple bugs in earlier versions of redis-py that were causing issues for Celery, we were forced to bump the minimum required version to 3.3.0.

Redis Result Backend

Due to multiple bugs in earlier versions of redis-py that were causing issues for Celery, we were forced to bump the minimum required version to 3.3.0.

DynamoDB Result Backend

The DynamoDB result backend has gained TTL support. As a result the minimum boto3 version was bumped to 1.9.178 which is the first version to support TTL for DynamoDB.

S3 Results Backend

To keep up with the current AWS API changes the minimum boto3 version was bumped to 1.9.125.

SQS Message Broker

To keep up with the current AWS API changes the minimum boto3 version was bumped to 1.9.125. ======== Django

Starting from this release, the minimum required version for Django is 1.11.

Configuration

CELERY_TASK_RESULT_EXPIRES has been replaced with CELERY_RESULT_EXPIRES.

3.10.4 News

Task Pools

Threaded Tasks Pool

We reintroduced a threaded task pool using concurrent.futures.ThreadPoolExecutor.

The previous threaded task pool was experimental. In addition it was based on the threadpool package which is obsolete.

You can use the new threaded task pool by setting worker_pool to ‘threads’ or by passing --pool threads to the celery worker command.
Result Backends

ElasticSearch Results Backend

HTTP Basic Authentication Support

You can now use HTTP Basic Authentication when using the ElasticSearch result backend by providing the username and the password in the URI. Previously, they were ignored and only unauthenticated requests were issued.

MongoDB Results Backend

Support for Authentication Source and Authentication Method

You can now specify the authSource and authMethod for the MongoDB using the URI options. The following URI does just that:

```
mongodb://user:password@example.com/?authSource=the_database&authMechanism=SCRAM-SHA-256
```

Refer to the documentation for details about the various options.

Canvas

Replacing Tasks Eagerly

You can now call `self.replace()` on tasks which are run eagerly. They will work exactly the same as tasks which are run asynchronously.

Chaining Groups

Chaining groups no longer result in a single group.

The following used to join the two groups into one. Now they correctly execute one after another:

```
>>> result = group(add.si(1, 2), add.si(1, 2)) | group(tsum.s(), tsum.s()).delay()
>>> result.get()
[6, 6]
```

3.11 API Reference

Release 4.4

Date Dec 16, 2019
3.11.1 celery — Distributed processing

This module is the main entry-point for the Celery API. It includes commonly needed things for calling tasks, and creating Celery applications.

<table>
<thead>
<tr>
<th>Celery</th>
<th>Celery application instance</th>
</tr>
</thead>
<tbody>
<tr>
<td>group</td>
<td>group tasks together</td>
</tr>
<tr>
<td>chain</td>
<td>chain tasks together</td>

</tbody>
</table>

Celery application objects

New in version 2.5.

```python
class celery.Celery(main=None, loader=None, backend=None, amqp=None, events=None, log=None, control=None, set_as_current=True, tasks=None, broker=None, include=None, changes=None, config_source=None, fixups=None, task_cls=None, autofinalize=True, namespace=None, strict_typing=True, **kwargs)
```

Celery application.

Parameters **main** *(str)* – Name of the main module if running as __main__. This is used as the prefix for auto-generated task names.

**Keyword Arguments**

* broker *(str)* – URL of the default broker used.
* backend *(Union[str, Type[celery.backends.baseBackend]])* – The result store backend class, or the name of the backend class to use.

Default is the value of the `result_backend` setting.

* autofinalize *(bool)* – If set to False a RuntimeError will be raised if the task registry or tasks are used before the app is finalized.

* set_as_current *(bool)* – Make this the global current app.
* include *(List[str])* – List of modules every worker should import.
* amqp *(Union[str, Type[AMQP]])* – AMQP object or class name.
* events *(Union[str, Type[celery.app.events.Events]])* – Events object or class name.
* log *(Union[str, Type[Logging]])* – Log object or class name.
* control *(Union[str, Type[celery.app.control.Control]])* – Control object or class name.
* tasks *(Union[str, Type[TaskRegistry]])* – A task registry, or the name of a registry class.
* fixups *(List[str])* – List of fix-up plug-ins (e.g., see celery.fixups.django).
• **config_source** *(Union[str, class])- Take configuration from a class, or object. Attributes may include any settings described in the documentation.

• **task_cls** *(Union[str, Type[celery.app.task.Task]])- base task class to use. See *this section* for usage.

**user_options = None**
Custom options for command-line programs. See *Adding new command-line options*

**steps = None**
Custom bootsteps to extend and modify the worker. See *Installing Bootsteps*.

**current_task**
Instance of task being executed, or None.

**current_worker_task**
The task currently being executed by a worker or None.

  Differs from **current_task** in that it’s not affected by tasks calling other tasks directly, or eagerly.

**amqp**
  
  Type AMQP related functionality

**backend**
Current backend instance.

**loader**
Current loader instance.

**control**
  
  Type Remote control

**events**
  
  Type Consuming and sending events

**log**
  
  Type *Logging*

**tasks**
Task registry.

**Warning:** Accessing this attribute will also auto-finalize the app.

**pool**
  
  Type Broker connection pool

**producer_pool**
Task
Base task class for this app.

timezone
Current timezone for this app.
This is a cached property taking the time zone from the `timezone` setting.

`builtin_fixups = {'celery.fixups.django:fixup'}`

oid
Universally unique identifier for this app.

close()
Clean up after the application.
Only necessary for dynamically created apps, and you should probably use the `with` statement instead.

Example

```python
>>> with Celery(set_as_current=False) as app:
...     with app.connection_for_write() as conn:
...         pass
```

`signature(*args, **kwargs)`
Return a new `Signature` bound to this app.

`bugreport()`
Return information useful in bug reports.

`config_from_object(obj, silent=False, force=False, namespace=None)`
Read configuration from object.
Object is either an actual object or the name of a module to import.

Example

```python
>>> celery.config_from_object('myapp.celeryconfig')
```

```python
>>> from myapp import celeryconfig
>>> celery.config_from_object(celeryconfig)
```

Parameters

- `silent (bool)` – If true then import errors will be ignored.
- `force (bool)` – Force reading configuration immediately. By default the configuration will be read only when required.

`config_from_envvar(variable_name, silent=False, force=False)`
Read configuration from environment variable.
The value of the environment variable must be the name of a module to import.
Example

```python
>>> os.environ['CELERY_CONFIG_MODULE'] = 'myapp.celeryconfig'
>>> celery.config_from_envvar('CELERY_CONFIG_MODULE')
```

**autodiscover_tasks** *(packages=None, related_name='tasks', force=False)*

Auto-discover task modules.

Searches a list of packages for a “tasks.py” module (or use related_name argument).

If the name is empty, this will be delegated to fix-ups (e.g., Django).

For example if you have a directory layout like this:

```plaintext
foo/__init__.py
   tasks.py
   models.py
bar/__init__.py
   tasks.py
   models.py
baz/__init__.py
   models.py
```

Then calling `app.autodiscover_tasks(['foo', 'bar', 'baz'])` will result in the modules `foo.tasks` and `bar.tasks` being imported.

**Parameters**

- **packages** *(List[str])* – List of packages to search. This argument may also be a callable, in which case the value returned is used (for lazy evaluation).

- **related_name** *(str)* – The name of the module to find. Defaults to “tasks”: meaning “look for ‘module.tasks’ for every module in packages.”. If None will only try to import the package, i.e. “look for ‘module’”.

- **force** *(bool)* – By default this call is lazy so that the actual auto-discovery won’t happen until an application imports the default modules. Forcing will cause the auto-discovery to happen immediately.

**add_defaults** *(fun)*

Add default configuration from dict `d`.

If the argument is a callable function then it will be regarded as a promise, and it won’t be loaded until the configuration is actually needed.

This method can be compared to:

```python
>>> celery.conf.update(d)
```

with a difference that 1) no copy will be made and 2) the dict will not be transferred when the worker spawns child processes, so it’s important that the same configuration happens at import time when pickle restores the object on the other side.

**add_periodic_task** *(schedule, sig, args=(), kwaargs=(), name=None, **opts)*

**setup_security** *(allowed_serializers=None, key=None, cert=None, store=None, digest='sha256', serializer='json')*

Setup the message-signing serializer.

This will affect all application instances (a global operation).
Disables untrusted serializers and if configured to use the auth serializer will register the auth serializer with the provided settings into the Kombu serializer registry.

**Parameters**

- `allowed_serializers (Set[str])` – List of serializer names, or content_types that should be exempt from being disabled.
- `key (str)` – Name of private key file to use. Defaults to the security_key setting.
- `cert (str)` – Name of certificate file to use. Defaults to the security_certificate setting.
- `store (str)` – Directory containing certificates. Defaults to the security_cert_store setting.
- `digest (str)` – Digest algorithm used when signing messages. Default is sha256.
- `serializer (str)` – Serializer used to encode messages after they’ve been signed. See task_serializer for the serializers supported. Default is json.

**start (argv=None)**

Run celery using argv.

Uses sys.argv if argv is not specified.

**task (**args, **opts)**

Decorator to create a task class out of any callable.

**Examples**

```python
@app.task
def refresh_feed(url):
    store_feed(feedparser.parse(url))
```

with setting extra options:

```python
@app.task(exchange='feeds')
def refresh_feed(url):
    return store_feed(feedparser.parse(url))
```

**Note:** App Binding: For custom apps the task decorator will return a proxy object, so that the act of creating the task is not performed until the task is used or the task registry is accessed.

If you’re depending on binding to be deferred, then you must not access any attributes on the returned object until the application is fully set up (finalized).

**send_task** (name, args=None, kwargs=None, countdown=None, eta=None, task_id=None, producer=None, connection=None, router=None, result_cls=None, expires=None, publisher=None, link=None, link_error=None, add_to_parent=True, group_id=None, retries=0, chord=None, reply_to=None, time_limit=None, soft_time_limit=None, root_id=None, parent_id=None, route_name=None, shadow=None, chain=None, task_type=None, **options)

Send task by name.

Supports the same arguments as Task.apply_async().

**Parameters**
• **name** (*str*) – Name of task to call (e.g., “tasks.add”).

• **result_cls** (*AsyncResult*) – Specify custom result class.

`gen_task_name` *(name, module)*

*AsyncResult*

Create new result instance.

See also:

`celery.result.AsyncResult`.

*GroupResult*

Create new group result instance.

See also:

`celery.result.GroupResult`.

`worker_main` *(argv=None)*

Run *celery worker* using *argv*.

Uses *sys.argv* if *argv* is not specified.

*Worker*

Worker application.

See also:

`Worker`.

*WorkController*

Embeddable worker.

See also:

`WorkController`.

*Beat*

*celery beat* scheduler application.

See also:

`Beat`.

`connection_for_read` *(url=None, **kwargs)*

Establish connection used for consuming.

See also:

`connection()` for supported arguments.

`connection_for_write` *(url=None, **kwargs)*

Establish connection used for producing.

See also:

`connection()` for supported arguments.

`connection` *(hostname=None, userid=None, password=None, virtual_host=None, port=None, ssl=None, connect_timeout=None, transport=None, transport_options=None, heartbeat=None, login_method=None, failover_strategy=None, **kwargs)*

Establish a connection to the message broker.

Please use `connection_for_read()` and `connection_for_write()` instead, to convey the intent of use for this connection.
Parameters

- **url** – Either the URL or the hostname of the broker to use.
- **hostname** *(str)* – URL. Hostname/IP-address of the broker. If a URL is used, then the other argument below will be taken from the URL instead.
- **userid** *(str)* – Username to authenticate as.
- **password** *(str)* – Password to authenticate with
- **virtual_host** *(str)* – Virtual host to use (domain).
- **port** *(int)* – Port to connect to.
- **ssl** *(bool, Dict)* – Defaults to the `broker_use_ssl` setting.
- **transport** *(str)* – Defaults to the `broker_transport` setting.
- **transport_options** *(Dict)* – Dictionary of transport specific options.
- **heartbeat** *(int)* – AMQP Heartbeat in seconds *(pyamqp only).*
- **login_method** *(str)* – Custom login method to use (AMQP only).
- **failover_strategy** *(str, Callable)* – Custom failover strategy.
- ****kwargs** – Additional arguments to `kombu.Connection`.

Returns the lazy connection instance.

Return type `kombu.Connection`

`connection_or_acquire` *(connection=None, pool=True, __, **__)*
Context used to acquire a connection from the pool.

For use within a `with` statement to get a connection from the pool if one is not already provided.

Parameters

- **connection** *(kombu.Connection)* – If not provided, a connection will be acquired from the connection pool.

`producer_or_acquire` *(producer=None)*
Context used to acquire a producer from the pool.

For use within a `with` statement to get a producer from the pool if one is not already provided.

Parameters

- **producer** *(kombu.Producer)* – If not provided, a producer will be acquired from the producer pool.

`select_queues` *(queues=None)*
Select subset of queues.

Parameters

- **queues** *(Sequence[str])* – a list of queue names to keep.

`now` *
Return the current time and date as a datetime.

`set_current` *
Make this the current app for this thread.

`set_default` *
Make this the default app for all threads.

`finalize` *(auto=False)*
Finalize the app.

This loads built-in tasks, evaluates pending task decorators, reads configuration, etc.
on_init()
Optional callback called at init.

prepare_config(c)
Prepare configuration before it is merged with the defaults.

on_configure
Signal sent when app is loading configuration.

on_after_configure
Signal sent after app has prepared the configuration.

on_after_finalize
Signal sent after app has been finalized.

on_after_fork
Signal sent in child process after fork.

Canvas primitives

See Canvas: Designing Work-flows for more about creating task work-flows.

class celery.group(*tasks, **options)
Creates a group of tasks to be executed in parallel.

A group is lazy so you must call it to take action and evaluate the group.

Note: If only one argument is passed, and that argument is an iterable then that’ll be used as the list of tasks instead: this allows us to use group with generator expressions.

Example

```python
>>> lazy_group = group([add.s(2, 2), add.s(4, 4)])
>>> promise = lazy_group()  # <-- evaluate: returns lazy result.
>>> promise.get()  # <-- will wait for the task to return
[4, 8]
```

Parameters

- **tasks (List[Signature])** – A list of signatures that this group will call. If there’s only one argument, and that argument is an iterable, then that’ll define the list of signatures instead.
- **options (Any)** – Execution options applied to all tasks in the group.

Returns

signature that when called will then call all of the tasks in the group (and return a GroupResult instance that can be used to inspect the state of the group).

Return type: group

class celery.chain(*tasks, **options)
Chain tasks together.

Each task follows one another, by being applied as a callback of the previous task.
Note: If called with only one argument, then that argument must be an iterable of tasks to chain: this allows us to use generator expressions.

Example

This is effectively \((2 + 2) + 4\):

```python
>>> res = chain(add.s(2, 2), add.s(4))()
8
```

Calling a chain will return the result of the last task in the chain. You can get to the other tasks by following the result.parent's:

```python
>>> res.parent.get()
4
```

Using a generator expression:

```python
>>> lazy_chain = chain(add.s(i) for i in range(10))
>>> res = lazy_chain(3)
```

Parameters *

*tasks* (Signature) – List of task signatures to chain. If only one argument is passed and that argument is an iterable, then that'll be used as the list of signatures to chain instead. This means that you can use a generator expression.

Returns

A lazy signature that can be called to apply the first task in the chain. When that task succeeds the next task in the chain is applied, and so on.

Return type *chain*

class celery.chord(header=None, body=None, task='celery.chord', args=None, kwargs=None, app=None, **options)

Barrier synchronization primitive.

A chord consists of a header and a body.

The header is a group of tasks that must complete before the callback is called. A chord is essentially a callback for a group of tasks.

The body is applied with the return values of all the header tasks as a list.

Example

The chord:

```python
>>> res = chord([add.s(2, 2), add.s(4, 4)])(sum_task.s())
```

is effectively \(\Sigma((2 + 2) + (4 + 4))\):

```python
>>> res.get()
12
```
celery.signature(varies, *args, **kwargs)

Create new signature.

- if the first argument is a signature already then it’s cloned.
- if the first argument is a dict, then a Signature version is returned.

Returns The resulting signature.

Return type Signature

class celery.Signature(task=None, args=None, kwargs=None, options=None, type=None, sub-task_type=None, immutable=False, app=None, **ex)

Task Signature.

Class that wraps the arguments and execution options for a single task invocation.

Used as the parts in a group and other constructs, or to pass tasks around as callbacks while being compatible with serializers with a strict type subset.

Signatures can also be created from tasks:

- Using the .signature() method that has the same signature as Task.apply_async:

  ```
  >>> add.signature(args=(1,), kwargs={'kw': 2}, options={})
  ```

- or the .s() shortcut that works for star arguments:

  ```
  >>> add.s(1, kw=2)
  ```

- the .s() shortcut does not allow you to specify execution options but there’s a chaining .set method that returns the signature:

  ```
  >>> add.s(2, 2).set(countdown=10).set.expires=30).delay()
  ```

Note: You should use signature() to create new signatures. The Signature class is the type returned by that function and should be used for isinstance checks for signatures.

See also:

Canvas: Designing Work-flows for the complete guide.

Parameters

- **task** (Union[Type[celery.app.task.Task], str]) – Either a task class/instance, or the name of a task.
- **args** (Tuple) – Positional arguments to apply.
- **kwargs** (Dict) – Keyword arguments to apply.
- **options** (Dict) – Additional options to Task.apply_async().

Note: If the first argument is a dict, the other arguments will be ignored and the values in the dict will be used instead:

```
>>> s = signature('tasks.add', args=(2, 2))
>>> signature(s)
{'task': 'tasks.add', args=(2, 2), kwargs={}, options={}}
```
Proxies

`celery.current_app`

The currently set app for this thread.

`celery.current_task`

The task currently being executed (only set in the worker, or when eager/apply is used).

Celery Application.

- **Proxies**
- **Functions**

### 3.11.2 Proxies

`celery.app.default_app = <Celery default>`

Proxy always returning the app set as default.

### 3.11.3 Functions

`celery.app.app_or_default(app=None)`

Function returning the app provided or the default app if none.

The environment variable `CELERY_TRACE_APP` is used to trace app leaks. When enabled an exception is raised if there is no active app.

`celery.app.enable_trace()`

Enable tracing of app instances.

`celery.app.disable_trace()`

Disable tracing of app instances.

### 3.11.4 celery.app.task

Task implementation: request context and the task base class.

```python
class celery.app.task.Task
    Task base class.
```

**Note:** When called tasks apply the `run()` method. This method must be defined by all tasks (that is unless the `__call__()` method is overridden).

`AsyncResult(task_id, **kwargs)`

GetAsyncResult instance for this kind of task.

**Parameters**

- `task_id (str)` – Task id to get result for.

**exception MaxRetriesExceededError (*args, **kwargs)**

The tasks max restart limit has been exceeded.
exception OperationalError
     Recoverable message transport connection error.

Request = 'celery.worker.request:Request'
     Request class used, or the qualified name of one.

Strategy = 'celery.worker.strategy:default'
     Execution strategy used, or the qualified name of one.

abstract = True
     Deprecated attribute abstract here for compatibility.

acks_late = False
     When enabled messages for this task will be acknowledged after the task has been executed, and not just before (the default behavior).

     Please note that this means the task may be executed twice if the worker crashes mid execution.

     The application default can be overridden with the task_acks_late setting.

acks_on_failure_or_timeout = True
     When enabled messages for this task will be acknowledged even if it fails or times out.

     Configuring this setting only applies to tasks that are acknowledged after they have been executed and only if task_acks_late is enabled.

     The application default can be overridden with the task_acks_on_failure_or_timeout setting.

add_to_chord(sig, lazy=False)
     Add signature to the chord the current task is a member of.

     New in version 4.0.

     Currently only supported by the Redis result backend.

Parameters

- sig (~@Signature) – Signature to extend chord with.
- lazy (bool) – If enabled the new task won’t actually be called, and sig.delay() must be called manually.

after_return(status, retval, task_id, args, kwargs, einfo)
     Handler called after the task returns.

Parameters

- status (str) – Current task state.
- retval (Any) – Task return value/exception.
- task_id (str) – Unique id of the task.
- args (Tuple) – Original arguments for the task.
- kwargs (Dict) – Original keyword arguments for the task.
- einfo (ExceptionInfo) – Exception information.

Returns
     The return value of this handler is ignored.

Return type
     None

apply(args=None, kwargs=None, link=None, link_error=None, task_id=None, retries=None, throw=None, logfile=None, loglevel=None, headers=None, **options)
     Execute this task locally, by blocking until the task returns.

Parameters
apply_async (args=None, kwargs=None, task_id=None, producer=None, link=None, link_error=None, shadow=None, **options)
Apply tasks asynchronously by sending a message.

Parameters

- **args** (*Tuple*) – The positional arguments to pass on to the task.
- **kwargs** (*Dict*) – The keyword arguments to pass on to the task.
- **countdown** (*float*) – Number of seconds into the future that the task should execute. Defaults to immediate execution.
- **eta** (*datetime*) – Absolute time and date of when the task should be executed. May not be specified if **countdown** is also supplied.
- **expires** (*float, datetime*) – Datetime or seconds in the future for the task should expire. The task won’t be executed after the expiration time.
- **shadow** (*str*) – Override task name used in logs/monitoring. Default is retrieved from **shadow_name()**.
- **connection** (*kombu.Connection*) – Re-use existing broker connection instead of acquiring one from the connection pool.
- **retry** (*bool*) – If enabled sending of the task message will be retried in the event of connection loss or failure. Default is taken from the **task_publish_retry** setting. Note that you need to handle the producer/connection manually for this to work.
- **retry_policy** (*Mapping*) – Override the retry policy used. See the **task_publish_retry_policy** setting.
- **queue** (*str, kombu.Queue*) – The queue to route the task to. This must be a key present in **task_queues**, or **task_create_missing_queues** must be enabled. See **Routing Tasks** for more information.
- **exchange** (*str, kombu.Exchange*) – Named custom exchange to send the task to. Usually not used in combination with the **queue** argument.
- **routing_key** (*str*) – Custom routing key used to route the task to a worker server. If in combination with a **queue** argument only used to specify custom routing keys to topic exchanges.
- **priority** (*int*) – The task priority, a number between 0 and 9. Defaults to the **priority** attribute.
- **serializer** (*str*) – Serialization method to use. Can be **pickle, json, yaml, msgpack** or any custom serialization method that’s been registered with **kombu.serialization.registry**. Defaults to the **serializer** attribute.
- **compression** (*str*) – Optional compression method to use. Can be one of **zlib, bzip2**, or any custom compression methods registered with **kombu.compression.register()**. Defaults to the **task_compression** setting.
• **link** (*Signature*) – A single, or a list of tasks signatures to apply if the task returns successfully.

• **link_error** (*Signature*) – A single, or a list of task signatures to apply if an error occurs while executing the task.

• **producer** (*kombu.Producer*) – custom producer to use when publishing the task.

• **add_to_parent** (*bool*) – If set to True (default) and the task is applied while executing another task, then the result will be appended to the parent tasks request.children attribute. Trailing can also be disabled by default using the **trail** attribute

• **publisher** (*kombu.Producer*) – Deprecated alias to **producer**.

• **headers** (*Dict*) – Message headers to be included in the message.

Returns Promise of future evaluation.

Return type **celery.result.AsyncResult**

Raises

• **TypeError** – If not enough arguments are passed, or too many arguments are passed. Note that signature checks may be disabled by specifying @task(**typing=False**).

• **kombu.exceptions.OperationalError** – If a connection to the transport cannot be made, or if the connection is lost.

Note: Also supports all keyword arguments supported by **kombu.Producer.publish()**.

**autoregister** = True

If disabled this task won’t be registered automatically.

**backend**

The result store backend used for this task.

**chunks** (*it, n*)

Create a **chunks** task for this task.

**default_retry_delay** = 180

Default time in seconds before a retry of the task should be executed. 3 minutes by default.

**delay** (*args, **kwargs*)

Star argument version of **apply_async()**.

Does not support the extra options enabled by **apply_async()**.

Parameters

• **args** (*Any*) – Positional arguments passed on to the task.

• **kwargs** (*Any*) – Keyword arguments passed on to the task.

Returns Future promise.

Return type **celery.result.AsyncResult**

**expires** = None

Default task expiry time.

**ignore_result** = False

If enabled the worker won’t store task state and return values for this task. Defaults to the **task_ignore_result** setting.
**map** *(it)*
Create a xmap task from it.

**max_retries = 3**
Maximum number of retries before giving up. If set to None, it will never stop retrying.

**name = None**
Name of the task.

**classmethod on_bound**(app)
Called when the task is bound to an app.

*Note:* This class method can be defined to do additional actions when the task class is bound to an app.

**on_failure**(exc, task_id, args, kwargs, einfo)
Error handler.
This is run by the worker when the task fails.

*Parameters*
- **exc** *(Exception)* – The exception raised by the task.
- **task_id** *(str)* – Unique id of the failed task.
- **args** *(Tuple)* – Original arguments for the task that failed.
- **kwargs** *(Dict)* – Original keyword arguments for the task that failed.
- **einfo** *(ExceptionInfo)* – Exception information.

*Returns* The return value of this handler is ignored.

*Return type* None

**on_retry**(exc, task_id, args, kwargs, einfo)
Retry handler.
This is run by the worker when the task is to be retried.

*Parameters*
- **exc** *(Exception)* – The exception sent to retry().
- **task_id** *(str)* – Unique id of the retried task.
- **args** *(Tuple)* – Original arguments for the retried task.
- **kwargs** *(Dict)* – Original keyword arguments for the retried task.
- **einfo** *(ExceptionInfo)* – Exception information.

*Returns* The return value of this handler is ignored.

*Return type* None

**on_success**(retval, task_id, args, kwargs)
Success handler.
Run by the worker if the task executes successfully.

*Parameters*
- **retval** *(Any)* – The return value of the task.
- **task_id** *(str)* – Unique id of the executed task.
• **args** (*Tuple*) – Original arguments for the executed task.

• **kwargs** (*Dict*) – Original keyword arguments for the executed task.

**Returns** The return value of this handler is ignored.

**Return type** None

**priority** = None

Default task priority.

**rate_limit** = None

*None* (no rate limit), ‘100/s’ (hundred tasks a second), ‘100/m’ (hundred tasks a minute), ‘100/h’ (hundred tasks an hour)

**Type** Rate limit for this task type. Examples

**reject_on_worker_lost** = None

Even if *acks_late* is enabled, the worker will acknowledge tasks when the worker process executing them abruptly exits or is signaled (e.g., KILL/INT, etc).

Setting this to true allows the message to be re-queued instead, so that the task will execute again by the same worker, or another worker.

Warning: Enabling this can cause message loops; make sure you know what you’re doing.

**replace** (*sig*)

Replace this task, with a new task inheriting the task id.

Execution of the host task ends immediately and no subsequent statements will be run.

New in version 4.0.

**Parameters** *sig* (*~@Signature*) – signature to replace with.

**Raises**

• **Ignore** – This is always raised when called in asynchronous context.

• It is best to always use `return self.replace(...)` to convey

• to the reader that the task won’t continue after being replaced.

**request**

Get current request object.

**request_stack** = `<celery.utils.threads._LocalStack object>`

Task request stack, the current request will be the topmost.

**resultrepr_maxsize** = 1024

Max length of result representation used in logs and events.

**retry** (*args=None, kwargs=None, exc=None, throw=True, eta=None, countdown=None, max_retries=None, **options*)

Retry the task, adding it to the back of the queue.

**Example**

```python
>>> from imaginary_twitter_lib import Twitter
>>> from proj.celery import app
```
>>> @app.task(bind=True)
... def tweet(self, auth, message):
...     twitter = Twitter(oauth=auth)
...     try:
...         twitter.post_status_update(message)
...     except twitter.FailWhale as exc:
...         # Retry in 5 minutes.
...         raise self.retry(countdown=60 * 5, exc=exc)

Note: Although the task will never return above as retry raises an exception to notify the worker, we use raise in front of the retry to convey that the rest of the block won’t be executed.

Parameters

- **args** (*Tuple*) – Positional arguments to retry with.
- **kwargs** (*Dict*) – Keyword arguments to retry with.
- **exc** (*Exception*) – Custom exception to report when the max retry limit has been exceeded (default: MaxRetriesExceededError).

If this argument is set and retry is called while an exception was raised (sys. exc_info() is set) it will attempt to re-raise the current exception.

If no exception was raised it will raise the exc argument provided.

- **countdown** (*float*) – Time in seconds to delay the retry for.
- **eta** (*datetime*) – Explicit time and date to run the retry at.
- **max_retries** (*int*) – If set, overrides the default retry limit for this execution. Changes to this parameter don’t propagate to subsequent task retry attempts. A value of None, means “use the default”. so if you want infinite retries you’d have to set the max_retries attribute of the task to None first.
- **time_limit** (*int*) – If set, overrides the default time limit.
- **soft_time_limit** (*int*) – If set, overrides the default soft time limit.
- **throw** (*bool*) – If this is False, don’t raise the Retry exception, that tells the worker to mark the task as being retried. Note that this means the task will be marked as failed if the task raises an exception, or successful if it returns after the retry call.
- **options** (*Any*) – Extra options to pass on to apply_async().

Raises celery.exceptions.Retry – To tell the worker that the task has been re-sent for retry. This always happens, unless the throw keyword argument has been explicitly set to False, and is considered normal operation.

run (*args, **kwargs*)
The body of the task executed by workers.

s (*args, **kwargs*)
Create signature.

Shortcut for .s(*a, **k) -> .signature(a, k).

send_event (type_, retry=True, retry_policy=None, **fields)
Send monitoring event message.
This can be used to add custom event types in Flower and other monitors.

**Parameters**

- **type** *(str)* – Type of event, e.g. "task-failed".

**Keyword Arguments**

- **retry** *(bool)* – Retry sending the message if the connection is lost. Default is taken from the task_publish_retry setting.
- **retry_policy** *(Mapping)* – Retry settings. Default is taken from the task_publish_retry_policy setting.
- **fields** *(Any)* – Map containing information about the event. Must be JSON serializable.

**send_events** = True
If enabled the worker will send monitoring events related to this task (but only if the worker is configured to send task related events). Note that this has no effect on the task-failure event case where a task is not registered (as it will have no task class to check this flag).

**serializer** = 'json'
The name of a serializer that are registered with kombu.serialization.registry. Default is 'pickle'.

**shadow_name** *(args, kwargs, options)*
Override for custom task name in worker logs/monitoring.

**Example**

```python
from celery.utils.imports import qualname

def shadow_name(task, args, kwargs, options):
    return qualname(args[0])

@app.task(shadow_name=shadow_name, serializer='pickle')
def apply_function_async(fun, *args, **kwargs):
    return fun(*args, **kwargs)
```

**Parameters**

- **args** *(Tuple)* – Task positional arguments.
- **kwargs** *(Dict)* – Task keyword arguments.
- **options** *(Dict)* – Task execution options.

**si** *(args, **kwargs)*
Create immutable signature.
Shortcut for .si(*a, **k) -> .signature(a, k, immutable=True).

**signature** *(args=None, *starargs, **starkwargs)*
Create signature.

**Returns**

- **object for** this task, wrapping arguments and execution options for a single task invocation.

**Return type** *signature*

**soft_time_limit** = None
Soft time limit. Defaults to the task_soft_time_limit setting.
starmap(it)
Create a xstarmap task from it.

store_errors_even_if_ignored = False
When enabled errors will be stored even if the task is otherwise configured to ignore results.

subtask(args=None, *starargs, **starkwargs)
Create signature.

Returns

object for this task, wrapping arguments and execution options for a single task invocation.

Return type signature

throws = ()
Tuple of expected exceptions.
These are errors that are expected in normal operation and that shouldn’t be regarded as a real error by the worker. Currently this means that the state will be updated to an error state, but the worker won’t log the event as an error.

time_limit = None
Hard time limit. Defaults to the task_time_limit setting.

track_started = False
If enabled the task will report its status as ‘started’ when the task is executed by a worker. Disabled by default as the normal behavior is to not report that level of granularity. Tasks are either pending, finished, or waiting to be retried.

Having a ‘started’ status can be useful for when there are long running tasks and there’s a need to report what task is currently running.

The application default can be overridden using the task_track_started setting.

trail = True
If enabled the request will keep track of subtasks started by this task, and this information will be sent with the result (result.children).

typing = True
Enable argument checking. You can set this to false if you don’t want the signature to be checked when calling the task. Defaults to Celery.strict_typing.

update_state(task_id=None, state=None, meta=None, **kwargs)
Update task state.

Parameters

• task_id (str) – Id of the task to update. Defaults to the id of the current task.
• state (str) – New state.
• meta (Dict) – State meta-data.

class celery.app.task.Context(*args, **kwargs)
Task request variables (Task.request).

celery.app.task.TaskType
alias of builtins.type

Sending/Receiving Messages (Kombu integration).
3.11.5 AMQP

class celery.app.amqp.AMQP(app)
    App AMQP API: app.amqp.

    Connection
    Broker connection class used. Default is kombu.Connection.

    Consumer
    Base Consumer class used. Default is kombu.Consumer.

    Producer
    Base Producer class used. Default is kombu.Producer.

    queues
    All currently defined task queues (a Queues instance).

    argsrepr_maxsize
    Max size of positional argument representation used for logging purposes. Default is 1024.

    kwargsrepr_maxsize
    Max size of keyword argument representation used for logging purposes. Default is 1024.

Queues (queues=None, create_missing=None, ha_policy=None, autoexchange=None, max_priority=None)

Router (queues=None, create_missing=None)
    Return the current task router.

flush_routes()
create_task_message
send_task_message
default_queue
default_exchange
producer_pool
router
routes

3.11.6 Queues

class celery.app.amqp.Queues(queues=None, default_exchange=None, create_missing=True, ha_policy=None, autoexchange=None, max_priority=None, default_routing_key=None)

    Queue name declaration mapping.

    Parameters
    • queues (Iterable) – Initial list/tuple or dict of queues.
- **create_missing** (*bool*) – By default any unknown queues will be added automatically, but if this flag is disabled the occurrence of unknown queues in `wanted` will raise `KeyError`.

- **ha_policy** (*Sequence, str*) – Default HA policy for queues with none set.

- **max_priority** (*int*) – Default x-max-priority for queues with none set.

`add(queue, **kwargs)`

Add new queue.

The first argument can either be a `kombu.Queue` instance, or the name of a queue. If the former the rest of the keyword arguments are ignored, and options are simply taken from the queue instance.

**Parameters**

- **queue** (*kombu.Queue, str*) – Queue to add.

- **exchange** (*kombu.Exchange, str*) – if queue is str, specifies exchange name.

- **routing_key** (*str*) – if queue is str, specifies binding key.

- **exchange_type** (*str*) – if queue is str, specifies type of exchange.

- ****options (*Any*) – Additional declaration options used when queue is a str.

`add_compat(name, **options)`

`consume_from`

Deselect queues so that they won’t be consumed from.

**Parameters**

- **exclude** (*Sequence[str], str*) – Names of queues to avoid consuming from.

`format(indent=0, indent_first=True)`

Format routing table into string for log dumps.

`new_missing(name)`

`select(include)`

Select a subset of currently defined queues to consume from.

**Parameters**

- **include** (*Sequence[str], str*) – Names of queues to consume from.

`select_add(queue, **kwargs)`

Add new task queue that’ll be consumed from.

The queue will be active even when a subset has been selected using the `celery worker -Q` option.

### 3.11.7 celery.app.defaults

Configuration introspection and defaults.

```python
class celery.app.defaults.Option(default=None, *args, **kwargs)
    Describes a Celery configuration option.
```

```python
    alt = None
    deprecate_by = None
    old = {}
    remove_by = None
```
to_python(value)

typemap = {'any': <function Option.<lambda>>, 'bool': <function strtobool>, 'dict':
celery.app.defaults.flatten(d, root='', keyfilter=<function _flatten_keys>)
Flatten settings.
celery.app.defaults.find(name, namespace='celery')
Find setting by name.

3.11.8 celery.app.control

Worker Remote Control Client.
Client for worker remote control commands. Server implementation is in celery.worker.control.

class celery.app.control.Inspect(destination=None, timeout=1.0, callback=None, connection=None, app=None, limit=None, pattern=None, matcher=None)
API for app.control.inspect.
active(safe=None)
active_queues()
app = None
clock()
conf(with_defaults=False)
hello(from_node, revoked=None)
memdump(samples=10)
memsample()
objgraph(type='Request', n=200, max_depth=10)
ping(destination=None)
query_task(*ids)
registered(*taskinfoitems)
registered_tasks(*taskinfoitems)
report()
reserved(safe=None)
revoked()
scheduled(safe=None)
stats()
class celery.app.control.Control(app=None)
Worker remote control client.
class Mailbox(namespace, type='direct', connection=None, clock=None, accept=None, serializer=None, producer_pool=None, queue_ttl=None, queue_expires=None, reply_queue_ttl=None, reply_queue_expires=10.0)
Process Mailbox.
Node(hostname=None, state=None, channel=None, handlers=None)
**abcask** *(command, kwagrs=None)*

**accept** = ['json']

**call** *(destination, command, kwagrs=None, timeout=None, callback=None, channel=None)*

**cast** *(destination, command, kwagrs=None)*

**connection** = None

**exchange** = None

**exchange_fmt** = '%s.pidbox'

**get_queue** *(hostname)*

**get_reply_queue** *

**multi_call** *(command, kwagrs=None, timeout=1, limit=None, callback=None, channel=None)*

**namespace** = None

**node_cls**

    alias of **Node**

**oid**

**producer_or_acquire** *(producer=None, channel=None)*

**producer_pool**

**reply_exchange** = None

**reply_exchange_fmt** = 'reply.%s.pidbox'

**reply_queue**

**serializer** = None

**type** = 'direct'

**add_consumer** *(queue, exchange=None, exchange_type='direct', routing_key=None, options=None, destination=None, **kwagrs)*

Tell all (or specific) workers to start consuming from a new queue.

Only the queue name is required as if only the queue is specified then the exchange/routing key will be set to the same name (like automatic queues do).

---

**Note:** This command does not respect the default queue/exchange options in the configuration.

---

**Parameters**

- **queue** *(str)* – Name of queue to start consuming from.

- **exchange** *(str)* – Optional name of exchange.

- **exchange_type** *(str)* – Type of exchange (defaults to ‘direct’) command to, when empty broadcast to all workers.

- **routing_key** *(str)* – Optional routing key.

- **options** *(Dict)* – Additional options as supported by `kombu.entity.Queue.from_dict()`.
See also:

broadcast() for supported keyword arguments.

autoscale(max, min, destination=None, **kwargs)
Change worker(s) autoscale setting.

See also:

Supports the same arguments as broadcast().

broadcast(command, arguments=None, destination=None, connection=None, reply=False, timeout=1.0, limit=None, callback=None, channel=None, pattern=None, matcher=None, **extra_kwargs)
Broadcast a control command to the celery workers.

Parameters

• command (str) – Name of command to send.
• arguments (Dict) – Keyword arguments for the command.
• destination (List) – If set, a list of the hosts to send the command to, when empty broadcast to all workers.
• connection (kombu.Connection) – Custom broker connection to use, if not set, a connection will be acquired from the pool.
• reply (bool) – Wait for and return the reply.
• timeout (float) – Timeout in seconds to wait for the reply.
• limit (int) – Limit number of replies.
• callback (Callable) – Callback called immediately for each reply received.
• pattern (str) – Custom pattern string to match
• matcher (Callable) – Custom matcher to run the pattern to match

cancel_consumer(queue, destination=None, **kwargs)
Tell all (or specific) workers to stop consuming from queue.

See also:

Supports the same arguments as broadcast().

disable_events(destination=None, **kwargs)
Tell all (or specific) workers to disable events.

See also:

Supports the same arguments as broadcast().

discard_all(connection=None)
Discard all waiting tasks.

This will ignore all tasks waiting for execution, and they will be deleted from the messaging server.

Parameters connection (kombu.Connection) – Optional specific connection instance to use. If not provided a connection will be acquired from the connection pool.

Returns the number of tasks discarded.

Return type int
election(id, topic, action=None, connection=None)
enable_events (destination=None, **kwargs)
Tell all (or specific) workers to enable events.

See also:
Supports the same arguments as broadcast().

heartbeat (destination=None, **kwargs)
Tell worker(s) to send a heartbeat immediately.

See also:
Supports the same arguments as broadcast().

inspect

ping (destination=None, timeout=1.0, **kwargs)
Ping all (or specific) workers.

Returns List of {'hostname': reply} dictionaries.

Return type List[Dict]

See also:
broadcast() for supported keyword arguments.

pool_grow (n=1, destination=None, **kwargs)
Tell all (or specific) workers to grow the pool by n.

See also:
Supports the same arguments as broadcast().

pool_restart (modules=None, reload=False, reloader=None, destination=None, **kwargs)
Restart the execution pools of all or specific workers.

Keyword Arguments

• modules (Sequence[str]) – List of modules to reload.
• reload (bool) – Flag to enable module reloading. Default is False.
• reloader (Any) – Function to reload a module.
• destination (Sequence[str]) – List of worker names to send this command to.

See also:
Supports the same arguments as broadcast().

pool_shrink (n=1, destination=None, **kwargs)
Tell all (or specific) workers to shrink the pool by n.

See also:
Supports the same arguments as broadcast().

purge (connection=None)
Discard all waiting tasks.

This will ignore all tasks waiting for execution, and they will be deleted from the messaging server.

Parameters connection (kombu.Connection) – Optional specific connection instance to use. If not provided a connection will be acquired from the connection pool.

Returns the number of tasks discarded.

Return type int
rate_limit (task_name, rate_limit, destination=None, **kwargs)
Tell workers to set a new rate limit for task by type.

Parameters

- **task_name** (str) – Name of task to change rate limit for.
- **rate_limit** (int, str) – The rate limit as tasks per second, or a rate limit string ('100/m', etc. see celery.task.base.Task.rate_limit for more information).

See also:
broadcast() for supported keyword arguments.

revoke (task_id, destination=None, terminate=False, signal='SIGTERM', **kwargs)
Tell all (or specific) workers to revoke a task by id.
If a task is revoked, the workers will ignore the task and not execute it after all.

Parameters

- **task_id** (str) – Id of the task to revoke.
- **terminate** (bool) – Also terminate the process currently working on the task (if any).
- **signal** (str) – Name of signal to send to process if terminate. Default is TERM.

See also:
broadcast() for supported keyword arguments.

shutdown (destination=None, **kwargs)
Shutdown worker(s).

See also:
Supports the same arguments as broadcast()

terminate (task_id, destination=None, signal='SIGTERM', **kwargs)
Tell all (or specific) workers to terminate a task by id.

See also:
This is just a shortcut to revoke() with the terminate argument enabled.

time_limit (task_name, soft=None, hard=None, destination=None, **kwargs)
Tell workers to set time limits for a task by type.

Parameters

- **task_name** (str) – Name of task to change time limits for.
- **soft** (float) – New soft time limit (in seconds).
- **hard** (float) – New hard time limit (in seconds).
- ****kwargs (Any) – arguments passed on to broadcast().

celery.app.control.flatten_reply (reply)
Flatten node replies.

Convert from a list of replies in this format:

```python
[{'a@example.com': reply},
 {'b@example.com': reply}]
```

into this format:
3.11.9 celery.app.registry

Registry of available tasks.

```python
{'a@example.com': reply,
 'b@example.com': reply}
```

**class celery.app.registry.TaskRegistry**

Map of registered tasks.

- **exception NotRegistered**
  The task ain’t registered.

- **filter_types**(type)

- **periodic()**

- **register**(task)
  Register a task in the task registry.
  The task will be automatically instantiated if not already an instance. Name must be configured prior to registration.

- **regular()**

- **unregister**(name)
  Unregister task by name.

  - **Parameters**
    name**(str)** – name of the task to unregister, or a celery.task.base.Task with a valid name attribute.

    - **Raises** celery.exceptions.NotRegistered – if the task is not registered.

3.11.10 celery.app.backends

Backend selection.

**celery.app.backends.by_name**(backend=None,
loader=None,
extension_namespace='celery.result_backends')

Get backend class by name/alias.

**celery.app.backends.by_url**(backend=None, loader=None)

Get backend class by URL.

3.11.11 celery.app.builtins

Built-in Tasks.

The built-in tasks are always available in all app instances.

3.11.12 celery.app.events

Implementation for the app.events shortcuts.

**class celery.app.events.Events**(app=None)

Implements app.events.
Dispatcher
Receiver
State
default_dispatcher (hostname=None, enabled=True, buffer_while_offline=False)
dispatcher_cls = 'celery.events.dispatcher:EventDispatcher'
receiver_cls = 'celery.events.receiver:EventReceiver'
state_cls = 'celery.events.state:State'

3.11.13 celery.app.log

Logging configuration.
The Celery instances logging section: Celery.log.
Sets up logging for the worker and other programs, redirects standard outs, colors log output, patches logging related compatibility fixes, and so on.
class celery.app.log.TaskFormatter (fmt=None, use_color=True)
    Formatter for tasks, adding the task name and id.
    format (record)
    Format the specified record as text.
    The record's attribute dictionary is used as the operand to a string formatting operation which yields the returned string. Before formatting the dictionary, a couple of preparatory steps are carried out. The message attribute of the record is computed using LogRecord.getMessage(). If the formatting string uses the time (as determined by a call to usesTime(), formatTime() is called to format the event time. If there is exception information, it is formatted using formatException() and appended to the message.
class celery.app.log.Logging (app)
    Application logging setup (app.log).
    already_setup = False
colored (logfile=None, enabled=None)
get_default_logger (name='celery', **kwargs)
redirect_stdouts (loglevel=None, name='celery.redirected')
redirect_stdouts_to_logger (logger, loglevel=None, stdout=True, stderr=True)
    Redirect sys.stdout and sys.stderr to logger.
Parameters
    • logger (logging.Logger) – Logger instance to redirect to.
    • loglevel (int, str) – The loglevel redirected message will be logged as.
setup (loglevel=None, logfile=None, redirect_stdouts=False, redirect_level='WARNING', colorize=None, hostname=None)
setup_handlers (logger, logfile, format, colorize, formatter=<class 'celery.utils.log.ColorFormatter'>, **kwargs)
setup_logger (name='celery', *args, **kwargs)
    Deprecated: No longer used.
setup_logging_subsystem (loglevel=None, logfile=None, format=None, colorize=None, hostname=None, **kwargs)
**setup_task_loggers** *(loglevel=None, logfile=None, format=None, colorize=None, propagate=False, **kwargs)*

Setup the task logger.

If *logfile* is not specified, then *sys.stderr* is used.

Will return the base task logger object.

**supports_color** *(colorize=None, logfile=None)*

### 3.11.14 celery.app.utils

```python
class celery.app.utils.Settings(changes=None, defaults=None, keys=None, prefix=None)
```

Celery settings object.

- `broker_read_url`
- `broker_url`
- `broker_write_url`
- `finalize()`
- `find_option(name, namespace='')`
  
  Search for option by name.

#### Example

```python
>>> from proj.celery import app
>>> app.conf.find_option('disable_rate_limits')
('worker', 'prefetch_multiplier', <Option: type->bool default->False>)
```

**Parameters**

- `name (str)` – Name of option, cannot be partial.
- `namespace (str)` – Preferred name-space (*None* by default).

**Returns** of *(namespace, key, type).*

**Return type** Tuple

- `find_value_for_key (name, namespace='celery')`
  
  Shortcut to `get_by_parts(*find_option(name)[:-1])`.

- `get_by_parts(*parts)`
  
  Return the current value for setting specified as a path.

#### Example

```python
>>> from proj.celery import app
>>> app.conf.get_by_parts('worker', 'disable_rate_limits')
False
```
humanize(with_defaults=False, censored=True)
    Return a human readable text showing configuration changes.

result_backend
table(with_defaults=False, censored=True)
task_default_exchange
task_default_routing_key
timezone
value_set_for(key)
without_defaults()
    Return the current configuration, but without defaults.

```
celery.app.utils.appstr(app)
    String used in __repr__ etc, to id app instances.

celery.app.utils.bugreport(app)
    Return a string containing information useful in bug-reports.

celery.app.utils.filter_hidden_settings(conf)
    Filter sensitive settings.

celery.app.utils.find_app(app, symbol_by_name=<function symbol_by_name>,
                           imp=<function import_from_cwd>)
    Find app by name.
```

3.11.15 celery.bootsteps

A directed acyclic graph of reusable components.

```
class celery.bootsteps.Blueprint(steps=None, name=None, on_start=None,
                                 on_close=None, on_stopped=None)
    Blueprint containing bootsteps that can be applied to objects.

    Parameters
    • Sequence[Union[str, Step]](steps) – List of steps.
    • name (str) – Set explicit name for this blueprint.
    • on_start (Callable) – Optional callback applied after blueprint start.
    • on_close (Callable) – Optional callback applied before blueprint close.
    • on_stopped (Callable) – Optional callback applied after blueprint stopped.
```

GraphFormatter
    alias of StepFormatter

alias

apply(parent, **kwargs)
    Apply the steps in this blueprint to an object.
    This will apply the __init__ and include methods of each step, with the object as argument:

    ```python
    step = Step(obj)
    ...
    step.include(obj)
    ```
For `StartStopStep` the services created will also be added to the objects `steps` attribute.

```python
claim_steps()
close(parent)
connect_with(other)
default_steps = {}
human_state()
info(parent)
join(timeout=None)
load_step(step)
name = None
restart(parent, method='stop', description='restarting', propagate=False)
send_all (parent, method, description=None, reverse=True, propagate=True, args=())
start(parent)
started = 0
state = None
state_to_name = {0: 'initializing', 1: 'running', 2: 'closing', 3: 'terminating'}
stop(parent, close=True, terminate=False)
```

```python
class celery.bootsteps.Step (parent, **kwargs)
    A Bootstep.

    The `__init__()` method is called when the step is bound to a parent object, and can as such be used to initialize attributes in the parent object at parent instantiation-time.

    alias

    conditional = False
        Set this to true if the step is enabled based on some condition.

create(parent)
    Create the step.

enabled = True
    This provides the default for `include_if()`.

include(parent)
include_if(parent)
    Return true if bootstrap should be included.

    You can define this as an optional predicate that decides whether this step should be created.

info(obj)

instantiate(name, *args, **kwargs)

label = None
    Optional short name used for graph outputs and in logs.

last = False
    This flag is reserved for the workers Consumer, since it is required to always be started last. There can only be one object marked last in every blueprint.
```
name = 'celery.bootsteps.Step'
Optional step name, will use qualname if not specified.

requires = ()
List of other steps that that must be started before this step. Note that all dependencies must be in the same blueprint.

class celery.bootsteps.StartStopStep(parent, **kwargs)
Bootstep that must be started and stopped in order.

close (parent)
include (parent)

name = 'celery.bootsteps.StartStopStep'

obj = None
Optional obj created by the create() method. This is used by StartStopStep to keep the original service object.

start (parent)
stop (parent)
terminate (parent)

class celery.bootsteps.ConsumerStep (parent, **kwargs)
Bootstep that starts a message consumer.

consumers = None
get_consumers (channel)

name = 'celery.bootsteps.ConsumerStep'
requires = ('celery.worker.consumer:Connection',)

shutdown (c)
start (c)
stop (c)

3.11.16 celery.result

Task results/state and results for groups of tasks.

class celery.result.ResultBase
Base class for results.

parent = None
Parent result (if part of a chain)

class celery.result.AsyncResult (id, backend=None, task_name=None, app=None, parent=None)
Query task state.

Parameters

• id (str) – See id.
• backend (Backend) – See backend.

exception TimeoutError
The operation timed out.
app = None
args
as_tuple()

backend = None
The task result backend to use.

build_graph(intermediate=False, formatter=None)

children
collect(intermediate=False, **kwargs)
Collect results as they return.

Iterator, like get() will wait for the task to complete, but will also followAsyncResult and
ResultSet returned by the task, yielding (result, value) tuples for each result in the tree.

An example would be having the following tasks:

```
from celery import group
from proj.celery import app

@app.task(trail=True)
def A(how_many):
    return group(B.s(i) for i in range(how_many))()

@app.task(trail=True)
def B(i):
    return pow2.delay(i)

@app.task(trail=True)
def pow2(i):
    return i ** 2
```

```
>>> from celery.result import ResultBase
>>> from proj.tasks import A

>>> result = A.delay(10)

>>> [v for v in result.collect() ... if not isinstance(v, (ResultBase, tuple))]
[0, 1, 4, 9, 16, 25, 36, 49, 64, 81]
```

**Note:** The Task.trail option must be enabled so that the list of children is stored in result.
children. This is the default but enabled explicitly for illustration.

**Yields** Tuple[AsyncResult, Any] – tuples containing the result instance of the child task, and the
return value of that task.

date_done
UTC date and time.

failed()
Return True if the task failed.

forget()
Forget the result of this task and its parents.
get (timeout=None, propagate=True, interval=0.5, no_ack=True, follow_parents=True, callback=None, on_message=None, on_interval=None, disable_sync_subtasks=True, EXCEPTION_STATES=frozenset({'RETRY', 'REVOKED', 'FAILURE'}), PROPAGATE_STATES=frozenset({'FAILURE', 'REVOKED'}))

Wait until task is ready, and return its result.

**Warning:** Waiting for tasks within a task may lead to deadlocks. Please read *Avoid launching synchronous subtasks*.

**Warning:** Backends use resources to store and transmit results. To ensure that resources are released, you must eventually call `get()` or `forget()` on EVERY `AsyncResult` instance returned after calling a task.

**Parameters**

- **timeout (float)** – How long to wait, in seconds, before the operation times out.
- **propagate (bool)** – Re-raise exception if the task failed.
- **interval (float)** – Time to wait (in seconds) before retrying to retrieve the result. Note that this does not have any effect when using the RPC/redis result store backends, as they don’t use polling.
- **no_ack (bool)** – Enable amqp no ack (automatically acknowledge message). If this is `False` then the message will not be acked.
- **follow_parents (bool)** – Re-raise any exception raised by parent tasks.
- **disable_sync_subtasks (bool)** – Disable tasks to wait for sub tasks this is the default configuration. CAUTION do not enable this unless you must.

** Raises**

- **celery.exceptions.TimeoutError** – If `timeout` isn’t `None` and the result does not arrive within `timeout` seconds.
- **Exception** – If the remote call raised an exception then that exception will be re-raised in the caller process.

get_leaf()

graph

id = None

The task’s UUID.

ignored

If True, task result retrieval is disabled.

info

Task return value.

**Note:** When the task has been executed, this contains the return value. If the task raised an exception, this will be the exception instance.

iterdeps (intermediate=False)
kwargs
maybe_reraise (propagate=True, callback=None)
maybe_throw (propagate=True, callback=None)
name
queue
ready ()
   Return True if the task has executed.
   If the task is still running, pending, or is waiting for retry then False is returned.
result
   Task return value.
   **Note:** When the task has been executed, this contains the return value. If the task raised an exception, this will be the exception instance.

retries
revoke (connection=None, terminate=False, signal=None, wait=False, timeout=None)
   Send revoke signal to all workers.
   Any worker receiving the task, or having reserved the task, must ignore it.
   **Parameters**
   • **terminate (bool)** – Also terminate the process currently working on the task (if any).
   • **signal (str)** – Name of signal to send to process if terminate. Default is TERM.
   • **wait (bool)** – Wait for replies from workers. The timeout argument specifies the seconds to wait. Disabled by default.
   • **timeout (float)** – Time in seconds to wait for replies when wait is enabled.
state
   The tasks current state.
   Possible values includes:
   **PENDING**
   The task is waiting for execution.
   **STARTED**
   The task has been started.
   **RETRY**
   The task is to be retried, possibly because of failure.
   **FAILURE**
   The task raised an exception, or has exceeded the retry limit. The result attribute then contains the exception raised by the task.
   **SUCCESS**
   The task executed successfully. The result attribute then contains the tasks return value.
status
The tasks current state.
Possible values includes:

**PENDING**
The task is waiting for execution.

**STARTED**
The task has been started.

**RETRY**
The task is to be retried, possibly because of failure.

**FAILURE**
The task raised an exception, or has exceeded the retry limit. The `result` attribute then contains the exception raised by the task.

**SUCCESS**
The task executed successfully. The `result` attribute then contains the tasks return value.

`successful()`
Return `True` if the task executed successfully.

`supports_native_join`

`task_id`
Compat. alias to `id`.

`then` *(callback, on_error=None, weak=False)*

`throw` *(*args, **kwargs)*

`traceback`
Get the traceback of a failed task.

`wait` *(timeout=None, propagate=True, interval=0.5, no_ack=True, follow_parents=True, callback=None, on_message=None, on_interval=None, disable_sync_subtasks=True, EXCEPTION_STATES=frozenset({'RETRY', 'REVOKED', 'FAILURE'}), PROPAGATE_STATES=frozenset({'FAILURE', 'REVOKED'}))*
Wait until task is ready, and return its result.

**Warning:** Waiting for tasks within a task may lead to deadlocks. Please read *Avoid launching synchronous subtasks.*

**Warning:** Backends use resources to store and transmit results. To ensure that resources are released, you must eventually call `get()` or `forget()` on EVERY `AsyncResult` instance returned after calling a task.

Parameters

- `timeout` *(float)* – How long to wait, in seconds, before the operation times out.
- `propagate` *(bool)* – Re-raise exception if the task failed.
- **interval** (*float*) – Time to wait (in seconds) before retrying to retrieve the result. Note that this does not have any effect when using the RPC/redis result store backends, as they don’t use polling.

- **no_ack** (*bool*) – Enable amqp no ack (automatically acknowledge message). If this is False then the message will not be acked.

- **follow_parents** (*bool*) – Re-raise any exception raised by parent tasks.

- **disable_sync_subtasks** (*bool*) – Disable tasks to wait for sub tasks this is the default configuration. CAUTION do not enable this unless you must.

**Raises**

- **celery.exceptions.TimeoutError** – if timeout isn’t None and the result does not arrive within timeout seconds.

- **Exception** – If the remote call raised an exception then that exception will be re-raised in the caller process.

### worker

```python
class celery.result.ResultSet(results, app=None, ready_barrier=None, **kwargs)
```

A collection of results.

**Parameters**

- **results** (*Sequence[AsyncResult]*) – List of result instances.

**Methods**

- **add(result)**
  Add AsyncResult as a new member of the set.
  Does nothing if the result is already a member.

- **app**

- **backend**

- **clear()**
  Remove all results from this set.

- **completed_count()**
  Task completion count.

  **Returns**

  - int

- **discard(result)**
  Remove result from the set if it is a member.
  Does nothing if it’s not a member.

- **failed()**
  Return true if any of the tasks failed.

  **Returns**

  - True if one of the tasks failed. (i.e., raised an exception)

  **Return type**

  - bool

- **forget()**
  Forget about (and possible remove the result of) all the tasks.

- **get(timeout=None, propagate=True, interval=0.5, callback=None, no_ack=True, on_message=None, disable_sync_subtasks=True, on_interval=None)**
  See `join()`.
This is here for API compatibility with `AsyncResult`, in addition it uses `join_native()` if available for the current result backend.

**iter_native** *(timeout=None, interval=0.5, no_ack=True, on_message=None, on_interval=None)*

New in version 2.2.

Note that this does not support collecting the results for different task types using different backends.

This is currently only supported by the amqp, Redis and cache result backends.

**iterate** *(timeout=None, propagate=True, interval=0.5)*

Deprecated method, use `get()` with a callback argument.

**join** *(timeout=None, propagate=True, interval=0.5, callback=None, no_ack=True, on_message=None, disable_sync_subtasks=True, on_interval=None)*

Gather the results of all tasks as a list in order.

---

**Note:** This can be an expensive operation for result store backends that must resort to polling (e.g., database).

You should consider using `join_native()` if your backend supports it.

---

**Warning:** Waiting for tasks within a task may lead to deadlocks. Please see *Avoid launching synchronous subtasks.*

---

**Parameters**

- **timeout** *(float)* – The number of seconds to wait for results before the operation times out.

- **propagate** *(bool)* – If any of the tasks raises an exception, the exception will be re-raised when this flag is set.

- **interval** *(float)* – Time to wait (in seconds) before retrying to retrieve a result from the set. Note that this does not have any effect when using the amqp result store backend, as it does not use polling.

- **callback** *(Callable)* – Optional callback to be called for every result received. Must have signature `(task_id, value)` No results will be returned by this function if a callback is specified. The order of results is also arbitrary when a callback is used. To get access to the result object for a particular id you’ll have to generate an index first: `index = {r.id: r for r in gres.results.values()}` Or you can create new result objects on the fly: `result = app.AsyncResult(task_id)` (both will take advantage of the backend cache anyway).

- **no_ack** *(bool)* – Automatic message acknowledgment (Note that if this is set to `False` then the messages will not be acknowledged).

- **disable_sync_subtasks** *(bool)* – Disable tasks to wait for sub tasks this is the default configuration. CAUTION do not enable this unless you must.

**Raises** `celery.exceptions.TimeoutError` – if `timeout` isn’t `None` and the operation takes longer than `timeout` seconds.
**Celery Documentation, Release 4.4.0**

**join_native** *(timeout=None, propagate=True, interval=0.5, callback=None, no_ack=True, on_message=None, on_interval=None, disable_sync_subtasks=True)*

Backend optimized version of `join()`.

New in version 2.2.

Note that this does not support collecting the results for different task types using different backends.

This is currently only supported by the amqp, Redis and cache result backends.

**maybe_reraise** *(callback=None, propagate=True)*

**maybe_throw** *(callback=None, propagate=True)*

**ready** *

Did all of the tasks complete? (either by success of failure).

**Returns** true if all of the tasks have been executed.

**Return type** bool

**remove** *(result)*

Remove result from the set; it must be a member.

**Raises** KeyError – if the result isn’t a member.

**results = None**

List of results in in the set.

**revoke** *(connection=None, terminate=False, signal=None, wait=False, timeout=None)*

Send revoke signal to all workers for all tasks in the set.

**Parameters**

- **terminate** *(bool)* – Also terminate the process currently working on the task (if any).
- **signal** *(str)* – Name of signal to send to process if terminate. Default is TERM.
- **wait** *(bool)* – Wait for replies from worker. The timeout argument specifies the number of seconds to wait. Disabled by default.
- **timeout** *(float)* – Time in seconds to wait for replies when the wait argument is enabled.

**successful** *

Return true if all tasks successful.

**Returns**

true if all of the tasks finished successfully (i.e. didn’t raise an exception).

**Return type** bool

**supports_native_join**

then *(callback, on_error=None, weak=False)*

**update** *(results)*

Extend from iterable of results.

**waiting** *

Return true if any of the tasks are incomplete.

**Returns**

true if one of the tasks are still waiting for execution.

**Return type** bool
class celery.result.GroupResult(id=None, results=None, parent=None, **kwargs)

Like ResultSet, but with an associated id.

This type is returned by `group`.

It enables inspection of the tasks state and return values as a single entity.

**Parameters**

- `id (str)` – The id of the group.
- `results (Sequence[AsyncResult])` – List of result instances.
- `parent (ResultBase)` – Parent result of this group.

`as_tuple()`

`children`

`delete (backend=None)`

Remove this result if it was previously saved.

`id = None`

The UUID of the group.

`classmethod restore (id, backend=None, app=None)`

Restore previously saved group result.

`results = None`

List/iterator of results in the group

`save (backend=None)`

Save group-result for later retrieval using `restore()`.

**Example**

```python
>>> def save_and_restore(result):
...     result.save()
...     result = GroupResult.restore(result.id)
```

class celery.result.EagerResult(id, ret_value, state, traceback=None)

Result that we know has already been executed.

`forget ()`

Forget the result of this task and its parents.

`get (timeout=None, propagate=True, disable_sync_subtasks=True, **kwargs)`

Wait until task is ready, and return its result.

**Warning:** Waiting for tasks within a task may lead to deadlocks. Please read *Avoid launching synchronous subtasks.*

**Warning:** Backends use resources to store and transmit results. To ensure that resources are released, you must eventually call `get()` or `forget()` on EVERY `AsyncResult` instance returned after calling a task.

**Parameters**
• **timeout (float)** – How long to wait, in seconds, before the operation times out.

• **propagate (bool)** – Re-raise exception if the task failed.

• **interval (float)** – Time to wait (in seconds) before retrying to retrieve the result. Note that this does not have any effect when using the RPC/redis result store backends, as they don’t use polling.

• **no_ack (bool)** – Enable amqp no ack (automatically acknowledge message). If this is False then the message will **not be acked**.

• **follow_parents (bool)** – Re-raise any exception raised by parent tasks.

• **disable_sync_subtasks (bool)** – Disable tasks to wait for sub tasks this is the default configuration. CAUTION do not enable this unless you must.

**Raises**

• **celery.exceptions.TimeoutError** – if timeout isn’t None and the result does not arrive within timeout seconds.

• **Exception** – If the remote call raised an exception then that exception will be re-raised in the caller process.

**ready ()**

Return True if the task has executed.

If the task is still running, pending, or is waiting for retry then False is returned.

**result**

The tasks return value.

**revoke (*args, **kwargs)**

Send revoke signal to all workers.

Any worker receiving the task, or having reserved the task, must ignore it.

**Parameters**

• **terminate (bool)** – Also terminate the process currently working on the task (if any).

• **signal (str)** – Name of signal to send to process if terminate. Default is TERM.

• **wait (bool)** – Wait for replies from workers. The timeout argument specifies the seconds to wait. Disabled by default.

• **timeout (float)** – Time in seconds to wait for replies when wait is enabled.

**state**

The tasks state.

**status**

The tasks state.

**supports_native_join**

then (**callback, on_error=None, weak=False**)

**traceback**

The traceback if the task failed.

**wait (timeout=None, propagate=True, disable_sync_subtasks=True, **kwargs)**

Wait until task is ready, and return its result.
Warning: Waiting for tasks within a task may lead to deadlocks. Please read *Avoid launching synchronous subtasks*.

Warning: Backends use resources to store and transmit results. To ensure that resources are released, you must eventually call `get()` or `forget()` on EVERY `AsyncResult` instance returned after calling a task.

Parameters

- **timeout** (*float*) – How long to wait, in seconds, before the operation times out.
- **propagate** (*bool*) – Re-raise exception if the task failed.
- **interval** (*float*) – Time to wait (in seconds) before retrying to retrieve the result. Note that this does not have any effect when using the RPC/redis result store backends, as they don’t use polling.
- **no_ack** (*bool*) – Enable amqp no ack (automatically acknowledge message). If this is `False` then the message will **not be acked**.
- **follow_parents** (*bool*) – Re-raise any exception raised by parent tasks.
- **disable_sync_subtasks** (*bool*) – Disable tasks to wait for sub tasks this is the default configuration. CAUTION do not enable this unless you must.

Raises

- **celery.exceptions.TimeoutError** – if `timeout` isn’t `None` and the result does not arrive within `timeout` seconds.
- **Exception** – If the remote call raised an exception then that exception will be re-raised in the caller process.

celery.result.result_from_tuple(*r, app=None*)

Deserialize result from tuple.

3.11.17 celery.schedules

Schedules define the intervals at which periodic tasks run.

**exception** celery.schedules.ParseException

Raised by `crontab_parser` when the input can’t be parsed.

class celery.schedules.schedule( *run_every=None, relative=False, nowfun=None, app=None*)

Schedule for periodic task.

Parameters

- **run_every** (*float, timedelta*) – Time interval.
- **relative** (*bool*) – If set to `True` the run time will be rounded to the resolution of the interval.
- **nowfun** (*Callable*) – Function returning the current date and time (*datetime*).
- **app** (*Celery*) – Celery app instance.

human_seconds
is_due (last_run_at)

Return tuple of (is_due, next_time_to_check).

Notes

- next time to check is in seconds.
- (True, 20), means the task should be run now, and the next time to check is in 20 seconds.
- (False, 12.3), means the task is not due, but that the scheduler should check again in 12.3 seconds.

The next time to check is used to save energy/CPU cycles, it does not need to be accurate but will influence the precision of your schedule. You must also keep in mind the value of beat_max_loop_interval, that decides the maximum number of seconds the scheduler can sleep between re-checking the periodic task intervals. So if you have a task that changes schedule at run-time then your next_run_at check will decide how long it will take before a change to the schedule takes effect. The max loop interval takes precedence over the next check at value returned.

Scheduler max interval variance

The default max loop interval may vary for different schedulers. For the default scheduler the value is 5 minutes, but for example the django-celery-beat database scheduler the value is 5 seconds.

relative = False

remaining_estimate (last_run_at)

seconds
class celery.schedules.crontab (minute='*', hour='*', day_of_week='*', day_of_month='*', month_of_year='*', **kwargs)

Crontab schedule.

A Crontab can be used as the run_every value of a periodic task entry to add crontab (5)-like scheduling.

Like a cron (5)-job, you can specify units of time of when you’d like the task to execute. It’s a reasonably complete implementation of cron’s features, so it should provide a fair degree of scheduling needs.

You can specify a minute, an hour, a day of the week, a day of the month, and/or a month in the year in any of the following formats:

minute

- A (list of) integers from 0-59 that represent the minutes of an hour of when execution should occur; or
- A string representing a Crontab pattern. This may get pretty advanced, like minute='*/15' (for every quarter) or minute='1,13,30-45,50-59/2'.

hour

- A (list of) integers from 0-23 that represent the hours of a day of when execution should occur; or
- A string representing a Crontab pattern. This may get pretty advanced, like hour='*/3' (for every three hours) or hour='0,8-17/2' (at midnight, and every two hours during office hours).

day_of_week

- A (list of) integers from 0-6, where Sunday = 0 and Saturday = 6, that represent the days of a week that execution should occur.
• A string representing a Crontab pattern. This may get pretty advanced, like `day_of_week='mon-fri'` (for weekdays only). (Beware that `day_of_week='*/2'` does not literally mean 'every two days', but 'every day that is divisible by two'!)

**day_of_month**

• A (list of) integers from 1-31 that represents the days of the month that execution should occur.

• A string representing a Crontab pattern. This may get pretty advanced, such as `day_of_month='2-30/2'` (for every even numbered day) or `day_of_month='1-7, 15-21'` (for the first and third weeks of the month).

**month_of_year**

• A (list of) integers from 1-12 that represents the months of the year during which execution can occur.

• A string representing a Crontab pattern. This may get pretty advanced, such as `month_of_year='*/3'` (for the first month of every quarter) or `month_of_year='2-12/2'` (for every even numbered month).

**nowfun**

Function returning the current date and time (`datetime`).

**app**

The Celery app instance.

It’s important to realize that any day on which execution should occur must be represented by entries in all three of the day and month attributes. For example, if `day_of_week` is 0 and `day_of_month` is every seventh day, only months that begin on Sunday and are also in the `month_of_year` attribute will have execution events. Or, `day_of_week` is 1 and `day_of_month` is '1-7,15-21' means every first and third Monday of every month present in `month_of_year`.

**is_due** (`last_run_at`)

Return tuple of (is_due, next_time_to_run).

**Note:** Next time to run is in seconds.

**SeeAlso:** `celery.schedules.scheduled.is_due()` for more information.

**remaining_delta** (`last_run_at`, `tz=None`, `ffwd=<class 'celery.utils.time.ffwd'>`)

**remaining_estimate** (`last_run_at`, `ffwd=<class 'celery.utils.time.ffwd'>`)

Estimate of next run time.

Returns when the periodic task should run next as a `timedelta`.

**class** `celery.schedules.crontab_parser` (`max_=60, min_=0`)

Parser for Crontab expressions.

Any expression of the form ‘groups’ (see BNF grammar below) is accepted and expanded to a set of numbers. These numbers represent the units of time that the Crontab needs to run on:

```
digit ::= '0'..'9'
dow ::= 'a'..'z'
number ::= digit+ | dow+
steps ::= number
range ::= number ( '-' number ) ?
umspec ::= '*' | range
expr ::= numspec ( '/' steps ) ?
groups ::= expr ( ',', expr ) *
```
The parser is a general purpose one, useful for parsing hours, minutes and day of week expressions. Example usage:

```python
>>> minutes = crontab_parser(60).parse('*/15')
[0, 15, 30, 45]
>>> hours = crontab_parser(24).parse('*/4')
[0, 4, 8, 12, 16, 20]
>>> day_of_week = crontab_parser(7).parse('*')
[0, 1, 2, 3, 4, 5, 6]
```

It can also parse day of month and month of year expressions if initialized with a minimum of 1. Example usage:

```python
>>> days_of_month = crontab_parser(31, 1).parse('*/3')
[1, 4, 7, 10, 13, 16, 19, 22, 25, 28, 31]
>>> months_of_year = crontab_parser(12, 1).parse('*/2')
[1, 3, 5, 7, 9, 11]
>>> months_of_year = crontab_parser(12, 1).parse('2-12/2')
[2, 4, 6, 8, 10, 12]
```

The maximum possible expanded value returned is found by the formula:

\[ \max + \min - 1 \]

**exception ParseException**

Raised by `crontab_parser` when the input can’t be parsed.

**parse** *(spec)*

celery.schedules.maybe_schedule *(s, relative=False, app=None)*

Return schedule from number, timedelta, or actual schedule.

class celery.schedules.solar *(event, lat, lon, **kwargs)*

Solar event.

A solar event can be used as the `run_every` value of a periodic task entry to schedule based on certain solar events.

**Notes**

Available event values are:

- `dawn_astronomical`
- `dawn_nautical`
- `dawn_civil`
- `sunrise`
- `solar_noon`
- `sunset`
- `dusk_civil`
- `dusk_nautical`
- `dusk_astronomical`

**Parameters**

- `event (str)` – Solar event that triggers this task. See note for available values.
• **lat** (*int*) – The latitude of the observer.

• **lon** (*int*) – The longitude of the observer.

• **nowfun** (*Callable*) – Function returning the current date and time as a class: `~datetime.datetime`.

• **app** (*Celery*) – Celery app instance.

**is_due** (*last_run_at*)

Return tuple of `(is_due, next_time_to_run)`.

**Note:** next time to run is in seconds.

See also:

`celery.schedules.schedule.is_due()` for more information.

**remaining_estimate** (*last_run_at*)

Return estimate of next time to run.

**Returns**

- **when the periodic task should** run next, or if it shouldn’t run today (e.g., the sun does not rise today), returns the time when the next check should take place.

**Return type** `timedelta`

### 3.11.18 celery.signals

Celery Signals.

This module defines the signals (Observer pattern) sent by both workers and clients.

Functions can be connected to these signals, and connected functions are called whenever a signal is called.

See also:

*Signals* for more information.

### 3.11.19 celery.security

Message Signing Serializer.

`celery.security.setup_security` (*allowed_serializers=None, key=None, cert=None, store=None, digest=None, serializer='json', app=None*)

See `Celery.setup_security()`.

### 3.11.20 celery.utils.debug

- **Sampling Memory Usage**
- **API Reference**
Sampling Memory Usage

This module can be used to diagnose and sample the memory usage used by parts of your application.

For example, to sample the memory usage of calling tasks you can do this:

```python
from celery.utils.debug import sample_mem, memdump
from tasks import add

try:
    for i in range(100):
        for j in range(100):
            add.delay(i, j)
            sample_mem()
finally:
    memdump()
```

API Reference

Utilities for debugging memory usage, blocking calls, etc.

`celery.utils.debug.sample_mem()`  
Sample RSS memory usage.
Statistics can then be output by calling `memdump()`.

`celery.utils.debug.memdump(samples=10, file=None)`  
Dump memory statistics.
Will print a sample of all RSS memory samples added by calling `sample_mem()`, and in addition print used RSS memory after `gc.collect()`.

`celery.utils.debug.sample(x, n, k=0)`  
Given a list \( x \) a sample of length \( n \) of that list is returned.
For example, if \( n \) is 10, and \( x \) has 100 items, a list of every tenth item is returned.
\( k \) can be used as offset.

`celery.utils.debug.mem_rss()`  
Return RSS memory usage as a humanized string.

`celery.utils.debug.ps()`  
Return the global `psutil.Process` instance.

Note: Returns None if `psutil` is not installed.

3.11.21 `celery.exceptions`

- Error Hierarchy

Celery error types.
Error Hierarchy

• Exception
  – celery.exceptions.CeleryError
    * ImproperlyConfigured
    * SecurityError
    * TaskPredicate
      · Ignore
      · Reject
      · Retry
    * TaskError
      · QueueNotFound
      ·IncompleteStream
      · NotRegistered
      · AlreadyRegistered
      · TimeoutError
      · MaxRetriesExceededError
      · TaskRevokedError
      · InvalidTaskError
      · ChordError
  – kombu.exceptions.KombuError
    * OperationalError
      Raised when a transport connection error occurs while sending a message (be it a task, remote control command error).

  Note: This exception does not inherit from CeleryError.

– billiard errors (prefork pool)
  * SoftTimeLimitExceeded
  * TimeLimitExceeded
  * WorkerLostError
  * Terminated

• UserWarning
  – CeleryWarning
    * AlwaysEagerIgnored
    * DuplicateNodenameWarning
    * FixupWarning
    * NotConfigured
• BaseException
  - SystemExit
    * WorkerTerminate
    * WorkerShutdown

exception celery.exceptions.CeleryWarning
  Base class for all Celery warnings.

exception celery.exceptions.AlwaysEagerIgnored
  send_task ignores task_always_eager option.

exception celery.exceptions.DuplicateNodenameWarning
  Multiple workers are using the same nodename.

exception celery.exceptions.FixupWarning
  Fixup related warning.

exception celery.exceptions.NotConfigured
  Celery hasn’t been configured, as no config module has been found.

exception celery.exceptions.CeleryError
  Base class for all Celery errors.

exception celery.exceptions.ImproperlyConfigured
  Celery is somehow improperly configured.

exception celery.exceptions.SecurityError
  Security related exception.

exception celery.exceptions.OperationalError
  Recoverable message transport connection error.

exception celery.exceptions.TaskPredicate
  Base class for task-related semi-predicates.

exception celery.exceptions.Ignore
  A task can raise this to ignore doing state updates.

exception celery.exceptions.Reject (reason=None, requeue=False)
  A task can raise this if it wants to reject/re-queue the message.

exception celery.exceptions.Retry (message=None, exc=None, when=None, **kwargs)
  The task is to be retried later.

    exc = None
      Exception (if any) that caused the retry to happen.

    humanize()

    message = None
      Optional message describing context of retry.

    when = None
      Time of retry (ETA), either numbers.Real or datetime.

exception celery.exceptions.TaskError
  Task related errors.

exception celery.exceptions.QueueNotFound
  Task routed to a queue not in conf.queues.
exception celery.exceptions.IncompleteStream
   Found the end of a stream of data, but the data isn’t complete.

exception celery.exceptions.NotRegistered
   The task ain’t registered.

exception celery.exceptions.AlreadyRegistered
   The task is already registered.

exception celery.exceptions.TimeoutError
   The operation timed out.

exception celery.exceptions.MaxRetriesExceededError(*args, **kwargs)
   The tasks max restart limit has been exceeded.

exception celery.exceptions.TaskRevokedError
   The task has been revoked, so no result available.

exception celery.exceptions.InvalidTaskError
   The task has invalid data or ain’t properly constructed.

exception celery.exceptions.ChordError
   A task part of the chord raised an exception.

exception celery.exceptions.SoftTimeLimitExceeded
   The soft time limit has been exceeded. This exception is raised to give the task a chance to clean up.

exception celery.exceptions.TimeLimitExceeded
   The time limit has been exceeded and the job has been terminated.

exception celery.exceptions.WorkerLostError
   The worker processing a job has exited prematurely.

exception celery.exceptions.Terminated
   The worker processing a job has been terminated by user request.

exception celery.exceptions.CPendingDeprecationWarning
   Warning of pending deprecation.

exception celery.exceptions.CDeprecationWarning
   Warning of deprecation.

exception celery.exceptions.WorkerShutdown
   Signals that the worker should perform a warm shutdown.

exception celery.exceptions.WorkerTerminate
   Signals that the worker should terminate immediately.

3.11.22 celery.loaders

Get loader by name.

Loaders define how configuration is read, what happens when workers start, when tasks are executed and so on.

celery.loaders.get_loader_cls(loader)
   Get loader class by name/alias.

3.11.23 celery.loaders.app

The default loader used with custom app instances.
class celery.loaders.app.AppLoader(app, **kwargs)
    Default loader used when an app is specified.

3.11.24 celery.loaders.default

The default loader used when no custom app has been initialized.

class celery.loaders.default.Loader(app, **kwargs)
    The loader used by the default app.
    
    read_configuration(fail_silently=True)
    Read configuration from celeryconfig.py.
    
    setup_settings(settingsdict)

3.11.25 celery.loaders.base

Loader base class.

class celery.loaders.base.BaseLoader(app, **kwargs)
    Base class for loaders.
    
    Loaders handles,
    
    • Reading celery client/worker configurations.
    
    • What happens when a task starts?  See on_task_init().
    
    • What happens when the worker starts?  See on_worker_init().
    
    • What happens when the worker shuts down?  See on_worker_shutdown().
    
    • What modules are imported to find tasks?
    
    autodiscover_tasks(packages, related_name='tasks')
    
    builtin_modules = frozenset()
    
    cmdline_config_parser(args, namespace='celery', re_type=re.compile(r'\((\w+)\)'), extra_types=None, override_types=None)
    
    conf
    Loader configuration.
    
    config_from_object(obj, silent=False)
    
    configured = False
    
    default_modules
    
    find_module(module)
    
    import_default_modules()
    
    import_from_cwd(module, imp=None, package=None)
    
    import_module(module, package=None)
    
    import_task_module(module)
    
    init_worker()
    
    init_worker_process()
    
    now(utc=True)
on_process_cleanup()
   Called after a task is executed.

on_task_init(task_id, task)
   Called before a task is executed.

on_worker_init()
   Called when the worker (celery worker) starts.

on_worker_process_init()
   Called when a child process starts.

on_worker_shutdown()
   Called when the worker (celery worker) shuts down.

override_backends = {}
read_configuration(env='CELERY_CONFIG_MODULE')
shutdown_worker()
worker_initialized = False

• States
• Sets
   – READY_STATES
   – UNREADY_STATES
   – EXCEPTION_STATES
   – PROPAGATE_STATES
   – ALL_STATES
• Misc

Built-in task states.

3.11.26 States
See States.

3.11.27 Sets

READY_STATES
Set of states meaning the task result is ready (has been executed).

UNREADY_STATES
Set of states meaning the task result is not ready (hasn’t been executed).
EXCEPTION_STATES

Set of states meaning the task returned an exception.

PROPAGATE_STATES

Set of exception states that should propagate exceptions to the user.

ALL_STATES

Set of all possible states.

3.11.28 Misc

celery.states.PENDING = 'PENDING'
    Task state is unknown (assumed pending since you know the id).

celery.states.RECEIVED = 'RECEIVED'
    Task was received by a worker (only used in events).

celery.states.STARTED = 'STARTED'
    Task was started by a worker (task_track_started).

celery.states.SUCCESS = 'SUCCESS'
    Task succeeded

celery.states.FAILURE = 'FAILURE'
    Task failed

celery.states.REVOKED = 'REVOKED'
    Task was revoked.

celery.states.RETRY = 'RETRY'
    Task is waiting for retry.

celery.states.precedence(state)
    Get the precedence index for state.
    Lower index means higher precedence.

class celery.states.state
    Task state.

    State is a subclass of str, implementing comparison methods adhering to state precedence rules:

    >>> from celery.states import state, PENDING, SUCCESS
    >>> state(PENDING) < state(SUCCESS)
    True

    Any custom state is considered to be lower than FAILURE and SUCCESS, but higher than any of the other built-in states:

    >>> state('PROGRESS') > state(STARTED)
    True

(continues on next page)
3.11.29 celery.contrib.abortable

Abortable Tasks.

Abortable tasks overview

For long-running Task’s, it can be desirable to support aborting during execution. Of course, these tasks should be built to support abortion specifically.

The AbortableTask serves as a base class for all Task objects that should support abortion by producers.

• Producers may invoke the abort() method on AbortableAsyncResult instances, to request abortion.
• Consumers (workers) should periodically check (and honor!) the is_aborted() method at controlled points in their task’s run() method. The more often, the better.

The necessary intermediate communication is dealt with by the AbortableTask implementation.

Usage example

In the consumer:

```python
from __future__ import absolute_import
from celery.contrib.abortable import AbortableTask
from celery.utils.log import get_task_logger
from proj.celery import app

logger = get_task_logger(__name__)

@app.task(bind=True, base=AbortableTask)
def long_running_task(self):
    results = []
    for i in range(100):
        # check after every 5 iterations...
        # (or alternatively, check when some timer is due)
        if not i % 5:
            if self.is_aborted():
                # respect aborted state, and terminate gracefully.
                logger.warning('Task aborted')
                return
            value = do_something_expensive(i)
            results.append(y)
```

(continues on next page)
logger.info('Task complete')
return results

In the producer:

```python
from __future__ import absolute_import
import time
from proj.tasks import MyLongRunningTask
def myview(request):
    # result is of type AbortableAsyncResult
    result = long_running_task.delay()
    # abort the task after 10 seconds
    time.sleep(10)
    result.abort()
```

After the `result.abort()` call, the task execution isn’t aborted immediately. In fact, it’s not guaranteed to abort at all. Keep checking `result.state` status, or call `result.get(timeout=)` to have it block until the task is finished.

**Note:** In order to abort tasks, there needs to be communication between the producer and the consumer. This is currently implemented through the database backend. Therefore, this class will only work with the database backends.

```python
class celery.contrib.abortable.AbortableAsyncResult(id, backend=None, task_name=None, app=None, parent=None)

 Represents an abortable result.

 Specifically, this gives the AsyncResult a `abort()` method, that sets the state of the underlying Task to 'ABORTED'.

 `abort()` Set the state of the task to ABORTED.

 Abortable tasks monitor their state at regular intervals and terminate execution if so.

 **Warning:** Be aware that invoking this method does not guarantee when the task will be aborted (or even if the task will be aborted at all).

 `is_aborted()` Return True if the task is (being) aborted.
```

```python
class celery.contrib.abortable.AbortableTask
 Task that can be aborted.

 This serves as a base class for all Task’s that support aborting during execution.

 All subclasses of AbortableTask must call the `is_aborted()` method periodically and act accordingly when the call evaluates to True.

 `AsyncResult(task_id)` Return the accompanying AbortableAsyncResult instance.

 `abstract = True`
is_aborted(**kwargs)
    Return true if task is aborted.

    Checks against the backend whether this AbortableAsyncResult is ABORTED.

    Always return False in case the task_id parameter refers to a regular (non-abortable) Task.

    Be aware that invoking this method will cause a hit in the backend (for example a database query), so find a good balance between calling it regularly (for responsiveness), but not too often (for performance).

3.11.30 celery.contrib.migrate

Message migration tools (Broker <-> Broker).

exception celery.contrib.migrate.StopFiltering
    Semi-predicate used to signal filter stop.

class celery.contrib.migrate.State
    Migration progress state.
    count = 0
    filtered = 0
    strtotal
    total_apx = 0

celery.contrib.migrate.republish(producer, message, exchange=None, routing_key=None, remove_props=None)
    Republish message.

celery.contrib.migrate.migrate_task(producer, body_, message, queues=None)
    Migrate single task message.

celery.contrib.migrate.migrate_tasks(source, dest, migrate=<function migrate_task>, app=None, queues=None, **kwargs)
    Migrate tasks from one broker to another.

celery.contrib.migrate.move(predicate, connection=None, exchange=None, routing_key=None, source=None, app=None, callback=None, limit=None, transform=None, **kwargs)
    Find tasks by filtering them and move the tasks to a new queue.

    Parameters

    • predicate (Callable) – Filter function used to decide the messages to move. Must accept the standard signature of (body, message) used by Kombu consumer callbacks. If the predicate wants the message to be moved it must return either:
      1) a tuple of (exchange, routing_key), or
      2) a Queue instance, or
      3) any other true value means the specified exchange and routing_key arguments will be used.

    • connection (kombu.Connection) – Custom connection to use.

    • source – List[Union[str, kombu.Queue]]: Optional list of source queues to use instead of the default (queues in task_queues). This list can also contain Queue instances.

    • exchange (str, kombu.Exchange) – Default destination exchange.

    • routing_key (str) – Default destination routing key.
Celery Documentation, Release 4.4.0

- **limit** *(int)* – Limit number of messages to filter.
- **callback** *(Callable)* – Callback called after message moved, with signature *(state, body, message)*.
- **transform** *(Callable)* – Optional function to transform the return value *(destination)* of the filter function.

Also supports the same keyword arguments as `start_filter()`.

To demonstrate, the `move_task_by_id()` operation can be implemented like this:

```python
def is_wanted_task(body, message):
    if body['id'] == wanted_id:
        return
    Queue('foo', exchange=Exchange('foo'), routing_key='foo')
move(is_wanted_task)
```

or with a transform:

```python
def transform(value):
    if isinstance(value, string_t):
        return Queue(value, Exchange(value), value)
    return value
move(is_wanted_task, transform=transform)
```

**Note:** The predicate may also return a tuple of *(exchange, routing_key)* to specify the destination to where the task should be moved, or a `Queue` instance. Any other true value means that the task will be moved to the default exchange/routing_key.

celery.contrib.migrate.task_id_eq(task_id, body, message)
Return true if task id equals task_id'.

celery.contrib.migrate.task_id_in(ids, body, message)
Return true if task id is member of set ids'.

celery.contrib.migrate.start_filter(app, conn, filter, limit=None, timeout=1.0, ack_messages=False, tasks=None, queues=None, call-back=None, forever=False, on_declare_queue=None, consume_from=None, state=None, accept=None, **kwargs)
Filter tasks.

celery.contrib.migrate.move_task_by_id(task_id, dest, **kwargs)
Find a task by id and move it to another queue.

**Parameters**

- **task_id** *(str)* – Id of task to find and move.
- **dest** *(str, kombu.Queue)*: Destination queue.
- **transform** *(Callable)* – Optional function to transform the return value *(destination)* of the filter function.
- ****kwargs (Any)** – Also supports the same keyword arguments as `move()`.
**celery.contrib.migrate.move_by_idmap** *(map, **kwargs)*

Move tasks by matching from a `task_id: queue` mapping.

Where `queue` is a queue to move the task to.

**Example**

```python
>>> move_by_idmap({
...     '5bee6e82-f4ac-468e-bd3d-13e8600250bc': Queue('name'),
...     'ada8652d-aef3-466b-abd2-becdaf1b82b3': Queue('name'),
...     '3a2b140d-7db1-41ba-ac90-c36a0ef4ab1f': Queue('name')},
...     queues=['hipri'])
```

**celery.contrib.migrate.move_by_taskmap** *(map, **kwargs)*

Move tasks by matching from a `task_name: queue` mapping.

`queue` is the queue to move the task to.

**Example**

```python
>>> move_by_taskmap({
...     'tasks.add': Queue('name'),
...     'tasks.mul': Queue('name'),
... })
```

**celery.contrib.migrate.move_direct** *(predicate, connection=None, exchange=None, routing_key=None, source=None, app=None, callback=None, limit=None, *args, transform=<function worker_direct>, **kwargs)*

Find tasks by filtering them and move the tasks to a new queue.

**Parameters**

- **predicate** *(Callable)* – Filter function used to decide the messages to move. Must accept the standard signature of `(body, message)` used by Kombu consumer callbacks. If the predicate wants the message to be moved it must return either:
  1) a tuple of `(exchange, routing_key)`, or
  2) a `Queue` instance, or
  3) any other true value means the specified `exchange` and `routing_key` arguments will be used.

- **connection** *(kombu.Connection)* – Custom connection to use.

- **source** – List[Union[str, kombu.Queue]]: Optional list of source queues to use instead of the default (queues in `task_queues`). This list can also contain Queue instances.

- **routing_key** *(str)* – Default destination routing key.

- **limit** *(int)* – Limit number of messages to filter.

- **callback** *(Callable)* – Callback called after message moved, with signature `(state, body, message)`.

- **transform** *(Callable)* – Optional function to transform the return value (destination) of the filter function.
Also supports the same keyword arguments as `start_filter()`.

To demonstrate, the `move_task_by_id()` operation can be implemented like this:

```python
def is_wanted_task(body, message):
    if body['id'] == wanted_id:
        return Queue('foo', exchange=Exchange('foo'), routing_key='foo')
move(is_wanted_task)
```

or with a transform:

```python
def transform(value):
    if isinstance(value, string_t):
        return Queue(value, Exchange(value), value)
    return value
move(is_wanted_task, transform=transform)
```

**Note:** The predicate may also return a tuple of `(exchange, routing_key)` to specify the destination to where the task should be moved, or a `Queue` instance. Any other true value means that the task will be moved to the default exchange/routing_key.

```python
celery.contrib.migrate.move_direct_by_id(task_id, dest, **kwargs)
```

Find a task by id and move it to another queue.

**Parameters**

- `task_id (str)` – Id of task to find and move.
- `transform (Callable)` – Optional function to transform the return value (destination) of the filter function.
- `**kwargs (Any)` – Also supports the same keyword arguments as `move()`.

### 3.11.31 celery.contrib.pytest

**API Reference**

Fixtures and testing utilities for `py.test`.

```python
celery.contrib.pytest.celery_app(request, celery_config, celery_parameters, celery_enable_logging, use_celery_app_trap)
```

Fixture creating a Celery application instance.

```python
celery.contrib.pytest.celery_config()
```

Redefine this fixture to configure the test Celery app.

The config returned by your fixture will then be used to configure the `celery_app()` fixture.
celery.contrib.pytest.celery_enable_logging()
    You can override this fixture to enable logging.

celery.contrib.pytest.celery_includes()
    You can override this include modules when a worker start.
    You can have this return a list of module names to import, these can be task modules, modules registering
    signals, and so on.

celery.contrib.pytest.celery_parameters()
    Redefine this fixture to change the init parameters of test Celery app.
    The dict returned by your fixture will then be used as parameters when instantiating Celery.

celery.contrib.pytest.celery_session_app(request, celery_config, celery_parameters, celery_enable_logging, use_celery_app_trap)
    Session Fixture: Return app for session fixtures.

celery.contrib.pytest.celery_session_worker(request, celery_session_app, celery_includes, celery_worker_pool, 
celery_worker_parameters)
    Session Fixture: Start worker that lives throughout test suite.

celery.contrib.pytest.celery_worker(request, celery_app, celery_includes, celery_worker_pool, 
celery_worker_parameters)
    Fixture: Start worker in a thread, stop it when the test returns.

celery.contrib.pytest.celery_worker_parameters()
    Redefine this fixture to change the init parameters of Celery workers.
    This can be used e. g. to define queues the worker will consume tasks from.
    The dict returned by your fixture will then be used as parameters when instantiating WorkController.

celery.contrib.pytest.celery_worker_pool()
    You can override this fixture to set the worker pool.
    The “solo” pool is used by default, but you can set this to return e.g. “prefork”.

celery.contrib.pytest.depends_on_current_app(celery_app)
    Fixture that sets app as current.

celery.contrib.pytest.pytest_configure(config)
    Register additional pytest configuration.

celery.contrib.pytest.use_celery_app_trap()
    You can override this fixture to enable the app trap.
    The app trap raises an exception whenever something attempts to use the current or default apps.

3.11.32 celery.contrib.sphinx

Sphinx documentation plugin used to document tasks.

Introduction

Usage

Add the extension to your docs/conf.py configuration module:
If you’d like to change the prefix for tasks in reference documentation then you can change the `celery_task_prefix` configuration value:

```
celery_task_prefix = '{task}' # < default
```

With the extension installed `autodoc` will automatically find task decorated objects (e.g. when using the automodule directive) and generate the correct (as well as add a `{task}` prefix), and you can also refer to the tasks using `:task:proj.tasks.add` syntax.

Use `.. autotask::` to alternatively manually document a task.

```
class celery.contrib.sphinx.TaskDirective(name, arguments, options, content, linenos, content_offset, block_text, state, state_machine)

Sphinx task directive.

get_signature_prefix(sig)
    May return a prefix to put before the object name in the signature.

class celery.contrib.sphinx.TaskDocumenter(directive, name, indent=")

Document task definitions.

classmethod can_document_member(member, membername, isattr, parent)
    Called to see if a member can be documented by this documenter.

check_module()
    Check if self.object is really defined in the module given by self.modname.

document_members(all_members=False)
    Generate reST for member documentation.
    If all_members is True, do all members, else those given by self.options.members.

format_args()
    Format the argument signature of self.object.
    Should return None if the object does not have a signature.
```

celery.contrib.sphinx.autodoc_skip_member_handler(app, what, name, obj, skip, options)
    Handler for autodoc-skip-member event.

celery.contrib.sphinx.setup(app)
    Setup Sphinx extension.

### 3.11.33 celery.contrib.testing.worker

- **API Reference**

**API Reference**

Embedded workers for integration tests.

```
class celery.contrib.testing.worker.TestWorkController(*args, **kwargs)
    Worker that can synchronize on being fully started.
```
ensure_started()

Wait for worker to be fully up and running.

**Warning:** Worker must be started within a thread for this to work, or it will block forever.

**on_consumer_ready**(consumer)

Callback called when the Consumer blueprint is fully started.

celery.contrib.testing.worker.setup_app_for_worker**(app, loglevel, logfile)**

Setup the app to be used for starting an embedded worker.

celery.contrib.testing.worker.start_worker**(app, concurrency=1, pool='solo', loglevel='error', logfile=None, perform_ping_check=True, ping_task_timeout=10.0, **kwargs)**

Start embedded worker.

Yields celery.app.worker.Worker – worker instance.

### 3.11.34 celery.contrib.testing.app

#### API Reference

Create Celery app instances used for testing.

celery.contrib.testing.app.DEFAULT_TEST_CONFIG = {'accept_content': {'json'}, 'broker_heartbeat': 0, 'broker_url': 'memory://', 'enable_utc': True, 'result_backend': 'cache+memory://', 'timezone': 'UTC', 'worker_hijack_root_logger': False, 'worker_log_color': False}

Contains the default configuration values for the test app.

celery.contrib.testing.app.TestApp**(name=None, config=None, enable_logging=False, set_as_current=False, log=<class 'celery.contrib.testing.app.UnitLogging'>, backend=None, broker=None, **kwargs)**

App used for testing.

class celery.contrib.testing.app.Trap

Trap that pretends to be an app but raises an exception instead.

This to protect from code that does not properly pass app instances, then falls back to the current_app.

class celery.contrib.testing.app.UnitLogging(*args, **kwargs)

Sets up logging for the test application.

celery.contrib.testing.app.set_trap**(app)**

Contextmanager that installs the trap app.

The trap means that anything trying to use the current or default app will raise an exception.

celery.contrib.testing.app.setup_default_app**(app, use_trap=False)**

Setup default app for testing.

Ensures state is clean after the test returns.
3.11.35 celery.contrib.testing.manager

API Reference

Integration testing utilities.

class celery.contrib.testing.manager.Manager(app, **kwargs)
    Test helpers for task integration tests.

class celery.contrib.testing.manager.ManagerMixin
    Mixin that adds Manager capabilities.

    assert_accepted(ids, interval=0.5, desc='waiting for tasks to be accepted', **policy)
    assert_received(ids, interval=0.5, desc='waiting for tasks to be received', **policy)

    async_result_tasks_in_progress_or_completed(async_results, interval=0.5,
    desc='waiting for tasks to be started or completed', **policy)

    assert_task_state_from_result(fun, results, interval=0.5, **policy)

    assert_task_worker_state(fun, ids, interval=0.5, **policy)

    ensure_not_for_a_while(fun, catch, desc='thing', max_retries=20, interval_start=0.1,
    interval_step=0.02, interval_max=1.0, emit_warning=False, **options)

    Make sure something does not happen (at least for a while).

    inspect(timeout=3.0)

    is_accepted(ids, **kwargs)

    is_received(ids, **kwargs)

    static is_result_task_in_progress(results, **kwargs)

    join(r, propagate=False, max_retries=10, **kwargs)

    missing_results(r)

    query_task_states(ids, timeout=0.5)

    query_tasks(ids, timeout=0.5)

    remark(s, sep='—')

    retry_over_time(*args, **kwargs)

    true_or_raise(fun, *args, **kwargs)

    wait_for(fun, catch, desc='thing', args=(), kwargs=None, errback=None, max_retries=10,
    interval_start=0.1, interval_step=0.5, interval_max=5.0, emit_warning=False, **options)

    Wait for event to happen.

    The catch argument specifies the exception that means the event has not happened yet.

exception celery.contrib.testing.manager.Sentinel
    Signifies the end of something.
Celery Documentation, Release 4.4.0

`celery.contrib.testing.manager.humanize_seconds(secs, prefix='', sep='', now='now', *, microseconds=True)`

Show seconds in human form.

For example, 60 becomes “1 minute”, and 7200 becomes “2 hours”.

**Parameters**

- `prefix (str)` – can be used to add a preposition to the output (e.g., ‘in’ will give ‘in 1 second’, but add nothing to ‘now’).
- `now (str)` – Literal ‘now’.
- `microseconds (bool)` – Include microseconds.

### 3.11.36 celery.contrib.testing.mocks

**API Reference**

Useful mocks for unit testing.

- `celery.contrib.testing.mocks.TaskMessage(name, id=None, args=(), kwargs=None, callbacks=None, errbacks=None, chain=None, shadow=None, utc=None, **options)`
  
  Create task message in protocol 2 format.

- `celery.contrib.testing.mocks.TaskMessage1(name, id=None, args=(), kwargs=None, callbacks=None, errbacks=None, chain=None, **options)`
  
  Create task message in protocol 1 format.

- `celery.contrib.testing.mocks.task_message_from_sig(app, sig, utc=True, TaskMessage=<function TaskMessage>)`
  
  Create task message from `celery.Signature`.

**Example**

```python
>>> m = task_message_from_sig(app, add.s(2, 2))
>>> amqp_client.basic_publish(m, exchange='ex', routing_key='rkey')
```

### 3.11.37 celery.contrib.rdb

Remote Debugger.

**Introduction**

This is a remote debugger for Celery tasks running in multiprocessing pool workers. Inspired by a lost post on dzone.com.
Usage

```python
from celery.contrib import rdb
from celery import task

@task()
def add(x, y):
    result = x + y
    rdb.set_trace()
    return result
```

Environment Variables

**CELERY_RDB_HOST**

Hostname to bind to. Default is ‘127.0.0.1’ (only accessible from localhost).

**CELERY_RDB_PORT**

Base port to bind to. Default is 6899. The debugger will try to find an available port starting from the base port. The selected port will be logged by the worker.

```python
celery.contrib.rdb.set_trace(frame=None)
Set break-point at current location, or a specified frame.

celery.contrib.rdb.debugger()
Return the current debugger instance, or create if none.

class celery.contrib.rdb.Rdb(host='127.0.0.1', port=6899, port_search_limit=100, port_skew=0, out=<_io.TextIOWrapper name='<stdout>' mode='w' encoding='UTF-8'>)
Remote debugger.
```

### 3.11.38 celery.events

Monitoring Event Receiver+Dispatcher.

Events is a stream of messages sent for certain actions occurring in the worker (and clients if `task_send_sent_event` is enabled), used for monitoring purposes.

```python
celery.events.Event(type, _fields=None, __dict__=<class 'dict'>, __now__=<built-in function time>, **fields)
Create an event.
```

**Notes**

An event is simply a dictionary: the only required field is `type`. A `timestamp` field will be set to the current time if not provided.
class celery.events.EventDispatcher(connection=None, hostname=None, enabled=True, channel=None, buffer_while_offline=True, app=None, serializer=None, groups=None, delivery_mode=1, buffer_group=None, buffer_limit=24, on_send_buffered=None)

Dispatches event messages.

Parameters

- **connection** *(kombu.Connection)* – Connection to the broker.
- **hostname** *(str)* – Hostname to identify ourselves as, by default uses the hostname returned by `anon_nodename()`.
- **groups** *(Sequence[str]*) – List of groups to send events for. `send()` will ignore send requests to groups not in this list. If this is `None`, all events will be sent. Example groups include "task" and "worker".
- **enabled** *(bool)* – Set to `False` to not actually publish any events, making `send()` a no-op.
- **channel** *(kombu.Channel)* – Can be used instead of `connection` to specify an exact channel to use when sending events.
- **buffer_while_offline** *(bool)* – If enabled events will be buffered while the connection is down. `flush()` must be called as soon as the connection is re-established.

**Note:** You need to `close()` this after use.

DISABLED_TRANSPORTS = {'sql'}

app = None

close()
    Close the event dispatcher.

disable()

enable()

extend_buffer(other)
    Copy the outbound buffer of another instance.

flush(errors=True, groups=True)
    Flush the outbound buffer.

on_disabled = None

on_enabled = None

publish(type, fields, producer, blind=False, Event=<function Event>, **kwargs)
    Publish event using custom Producer.

Parameters

- **type** *(str)* – Event type name, with group separated by dash (-). fields: Dictionary of event fields, must be json serializable.
- **producer** *(kombu.Producer)* – Producer instance to use: only the publish method will be called.
- **retry** *(bool)* – Retry in the event of connection failure.
• **retry_policy** *(Mapping)* – Map of custom retry policy options. See `ensure()`.

• **blind** *(bool)* – Don’t set logical clock value (also don’t forward the internal logical clock).

• **Event** *(Callable)* – Event type used to create event. Defaults to `Event()`.

• **utcoffset** *(Callable)* – Function returning the current utc offset in hours.

**publisher**

**send** *(type, blind=False, utcoffset=<function utcoffset>, retry=False, retry_policy=None, Event=<function Event>, **fields)*

Send event.

**Parameters**

• **type** *(str)* – Event type name, with group separated by dash (-).

• **retry** *(bool)* – Retry in the event of connection failure.

• **retry_policy** *(Mapping)* – Map of custom retry policy options. See `ensure()`.

• **blind** *(bool)* – Don’t set logical clock value (also don’t forward the internal logical clock).

• **Event** *(Callable)* – Event type used to create event, defaults to `Event()`.

• **utcoffset** *(Callable)* – Function returning the current utc offset in hours.

• ****fields** *(Any)* – Event fields – must be json serializable.

**class celery.events.EventReceiver** *(channel, handlers=None, routing_key='#', node_id=None, app=None, queue_prefix=None, accept=None, queue_ttl=None, queue_expires=None)*

Capture events.

**Parameters**

• **connection** *(kombu.Connection)* – Connection to the broker.

• **handlers** *(Mapping[Callable])* – Event handlers. This is a map of event type names and their handlers. The special handler “*” captures all events that don’t have a handler.

**app = None**

**capture** *(limit=None, timeout=None, wakeup=True)*

Open up a consumer capturing events.

This has to run in the main process, and it will never stop unless `EventDispatcher.should_stop` is set to True, or forced via `KeyboardInterrupt` or `SystemExit`.

**connection**

**event_from_message** *(body, localize=True, now=<built-in function time>, tz-fields=operator.itemgetter('utcoffset', 'timestamp'), adjust_timestamp=<function adjust_timestamp>, CLIENT_CLOCK_SKEW=-1)*

**get_consumers** *(Consumer, channel)*

**itercapture** *(limit=None, timeout=None, wakeup=True)*

**on_consume_ready** *(connection, channel, consumers, wakeup=True, **kwargs)*
process(\textit{type, event})

Process event by dispatching to configured handler.

\texttt{wakeup\_workers(\textit{channel=None})}

\texttt{celery.events.get\_exchange}(\textit{conn, name='celeryev'})

Get exchange used for sending events.

\textbf{Parameters}

- \texttt{\textit{conn} (kombu.Connection)} – Connection used for sending/receiving events.
- \texttt{\textit{name} (str)} – Name of the exchange. Default is \texttt{celeryev}.

\textit{Note:} The event type changes if Redis is used as the transport (from topic -> fanout).

celery.events.group\_from\((\textit{type})\)

Get the group part of an event type name.

\textbf{Example}

\begin{verbatim}
>>> group_from('task-sent')
'task'

>>> group_from('custom-my-event')
'custom'
\end{verbatim}

\section*{3.11.39 \texttt{celery.events.receiver}}

Event receiver implementation.

\texttt{class celery.events.receiver.EventReceiver(\textit{\texttt{channel}, \texttt{handlers=None}, \texttt{routing\_key='#', \texttt{node\_id=None}, \texttt{app=None}, \texttt{queue\_prefix=None}, \texttt{accept=None}, \texttt{queue\_ttl=None}, \texttt{queue\_expires=None}}))}

Capture events.

\textbf{Parameters}

- \texttt{\textit{connection} (kombu.Connection)} – Connection to the broker.
- \texttt{\textit{handlers} (Mapping[Callable])} – Event handlers. This is a map of event type names and their handlers. The special handler “*” captures all events that don’t have a handler.

\texttt{app = None}

\texttt{capture(\textit{limit=None, timeout=None, wakeup=True})}

Open up a consumer capturing events.

This has to run in the main process, and it will never stop unless \texttt{EventDispatcher.\_should\_stop} is set to True, or forced via \texttt{KeyboardInterrupt} or \texttt{SystemExit}.
Celery Documentation, Release 4.4.0

```
from celery.events import get_consumers

get_consumers(Consumer, channel)
```

### celery.events.state

Event dispatcher sends events.

```
class celery.events.dispatcher.EventDispatcher
```

Dispatches event messages.

**Parameters**

- **connection** *(kombu.Connection)* – Connection to the broker.
- **hostname** *(str)* – Hostname to identify ourselves as, by default uses the hostname returned by `anon_nodename()`.
- **groups** *(Sequence[ str])* – List of groups to send events for. `send()` will ignore send requests to groups not in this list. If this is None, all events will be sent. Example groups include "task" and "worker".
- **enabled** *(bool)* – Set to False to not actually publish any events, making `send()` a no-op.
- **channel** *(kombu.Channel)* – Can be used instead of `connection` to specify an exact channel to use when sending events.
- **buffer_while_offline** *(bool)* – If enabled events will be buffered while the connection is down. `flush()` must be called as soon as the connection is re-established.

**Note:** You need to `close()` this after use.

```
DISABLED_TRANSPORTS = {'sql'}
```

**app** = None

```
close()
```

Close the event dispatcher.

```
disable()
```

```
enable()
```
**extend_buffer** *(other)*
Copy the outbound buffer of another instance.

**flush** *(errors=True, groups=True)*
Flush the outbound buffer.

```
on_disabled = None
on_enabled = None
```

**publish** *(type, fields, producer, blind=False, Event=<function Event>, **kwargs)*
Publish event using custom **Producer**.

**Parameters**

- **type** *(str)* – Event type name, with group separated by dash (-). fields: Dictionary of event fields, must be json serializable.
- **producer** *(kombu.Producer)* – Producer instance to use: only the publish method will be called.
- **retry** *(bool)* – Retry in the event of connection failure.
- **retry_policy** *(Mapping)* – Map of custom retry policy options. See **ensure()**.
- **blind** *(bool)* – Don’t set logical clock value (also don’t forward the internal logical clock).
- **Event** *(Callable)* – Event type used to create event. Defaults to **Event()**.
- **utcoffset** *(Callable)* – Function returning the current utc offset in hours.

**publisher**

**send** *(type, blind=False, utcoffset=<function utcoffset>, retry=False, retry_policy=None, Event=<function Event>, **fields)*
Send event.

**Parameters**

- **type** *(str)* – Event type name, with group separated by dash (-).
- **retry** *(bool)* – Retry in the event of connection failure.
- **retry_policy** *(Mapping)* – Map of custom retry policy options. See **ensure()**.
- **blind** *(bool)* – Don’t set logical clock value (also don’t forward the internal logical clock).
- **Event** *(Callable)* – Event type used to create event, defaults to **Event()**.
- **utcoffset** *(Callable)* – Function returning the current utc offset in hours.
- ****fields** *(Any)* – Event fields – must be json serializable.

### 3.11.41 celery.events.event

Creating events, and event exchange definition.

**celery.events.event.Event** *(type, _fields=None, __dict__=<class 'dict'>, __now__=<built-in function time>, **fields)*
Create an event.
Notes

An event is simply a dictionary: the only required field is `type`. A `timestamp` field will be set to the current time if not provided.

```python
celery.events.event.event_exchange = <unbound Exchange celeryev(topic)>
```
Exchange used to send events on. Note: Use `get_exchange()` instead, as the type of exchange will vary depending on the broker connection.

```python
celery.events.event.get_exchange(conn, name='celeryev')
```
Get exchange used for sending events.

**Parameters**

- `conn (kombu.Connection)` – Connection used for sending/receiving events.
- `name (str)` – Name of the exchange. Default is `celeryev`.

**Note:** The event type changes if Redis is used as the transport (from topic -> fanout).

```python
celery.events.event.group_from(type)
```
Get the group part of an event type name.

**Example**

```python
>>> group_from('task-sent')
'task'
```

```python
>>> group_from('custom-my-event')
'custom'
```

### 3.11.42 celery.events.state

In-memory representation of cluster state.

This module implements a data-structure used to keep track of the state of a cluster of workers and the tasks it is working on (by consuming events).

For every event consumed the state is updated, so the state represents the state of the cluster at the time of the last event.

Snapshots (`celery.events.snapshot`) can be used to take “pictures” of this state at regular intervals to for example, store that in a database.

```python
class celery.events.state.Worker(hostname=None, pid=None, freq=60, heartbeats=None, clock=0, active=None, processed=None, loadavg=None, sw_ident=None, sw_ver=None, sw_sys=None)
```
Worker State.

- `active`
- `alive`
- `clock`
- `event`
- `expire_window = 200`
freq
heartbeat_expires
heartbeat_max = 4
heartbeats
hostname
id
loadavg
pid
processed
status_string
sw_ident
sw_sys
sw_ver
update(f, **kw)

class celery.events.state.Task(uuid=none, cluster_state=none, children=none, **kwargs)

Task State.

args = None
as_dict()
client = None
clock = 0
eta = None

event(type_, timestamp=None, local_received=None, fields=None, precedence=<function precedence>, items=<function items>, setattr=<builtin function setattr>,
task_event_to_state=<builtin method get of dict object>, RETRY='RETRY')

exception = None
exchange = None
expires = None
failed = None

id

info(fields=None, extra=None)

Information about this task suitable for on-screen display.

kwargs = None

merge_rules = {'RECEIVED': ('name', 'args', 'kwargs', 'parent_id', 'root_id', 'retries')}

How to merge out of order events. Disorder is detected by logical ordering (e.g., task-received
must've happened before a task-failed event).

A merge rule consists of a state and a list of fields to keep from that state. (RECEIVED, ('name',
'args'), means the name and args fields are always taken from the RECEIVED state, and any values
for these fields received before or after is simply ignored.

name = None
origin
parent

status_string
sw_ident
sw_sys
sw_ver
update(f, **kw)

alive_workers()
Return a list of (seemingly) alive workers.
clear(ready=True)
clear_tasks(ready=True)
event(event)
event_count = 0
freeze_while(fun, *args, **kwargs)

get_or_create_task(uuid)
Get or create task by uuid.

get_or_create_worker(hostname, **kwargs)
Get or create worker by hostname.

Returns of (worker, was_created) pairs.
Return type Tuple

heap_multiplier = 4
itertasks(limit=None)

rebuild_taskheap(timetuple=<class 'kombu.clocks.timetuple'>)
task_count = 0
task_event(type_, fields)
Deprecated, use event().
task_types()
Return a list of all seen task types.
tasks_by_time(limit=None, reverse=True)
Generator yielding tasks ordered by time.
Yields Tuples of (uuid, Task).

3.11. API Reference 365
tasks_by_timestamp(limit=None, reverse=True)
Generator yielding tasks ordered by time.
Yields Tuples of (uuid, Task).
worker_event(type_, fields)
Deprecated, use event().
celery.events.state.heartbeat_expires(timestamp, freq=60, expire_window=200, Decimal=class 'decimal.Decimal', float=class 'float', isinstance=<built-in function isinstance>)
Return time when heartbeat expires.

3.11.43 celery.beat

The periodic task scheduler.

exception celery.beat.SchedulingError
An error occurred while scheduling a task.

class celery.beat.ScheduleEntry(name=None, task=None, last_run_at=None, total_run_count=None, schedule=None, args=(), kwargs=None, options=None, relative=False, app=None)
An entry in the scheduler.

Parameters
• name (str) – see name.
• schedule (schedule) – see schedule.
• args (Tuple) – see args.
• kwargs (Dict) – see kwargs.
• options (Dict) – see options.
• last_run_at (datetime) – see last_run_at.
• total_run_count (int) – see total_run_count.
• relative (bool) – Is the time relative to when the server starts?

args = None
Positional arguments to apply.
default_now()
editable_fields_equal(other)
is_due()
See is_due().
kwargs = None
Keyword arguments to apply.
last_run_at = None
The time and date of when this task was last scheduled.
name = None
The task name
next(last_run_at=None)
Return new instance, with date and count fields updated.
options = None
    Task execution options.

schedule = None
    The schedule (schedule)

total_run_count = 0
    Total number of times this task has been scheduled.

update (other)
    Update values from another entry.

    Will only update “editable” fields: task, schedule, args, kwargs, options.

class celery.beat.Scheduler (app, schedule=None, max_interval=None, Producer=None, lazy=False, sync_every_tasks=None, **kwargs)
    Scheduler for periodic tasks.

    The celery beat program may instantiate this class multiple times for introspection purposes, but then with
    the lazy argument set. It’s important for subclasses to be idempotent when this argument is set.

    Parameters
    • schedule (schedule) – see schedule.
    • max_interval (int) – see max_interval.
    • lazy (bool) – Don’t set up the schedule.

Entry
    alias of ScheduleEntry

add (**kwargs)
adjust (n, drift=-0.01)
apply_async (entry, producer=None, advance=True, **kwargs)
apply_entry (entry, producer=None)
close ()
connection
get_schedule ()
info
install_default_entries (data)
is_due (entry)
logger = <Logger celery.beat (WARNING)>
max_interval = 300
    Maximum time to sleep between re-checking the schedule.
merge_inplace (b)
populate_heap (event_t=<class 'celery.beat.event_t'>, heapify=<built-in function heapify>)
    Populate the heap with the data contained in the schedule.
producer
reserve (entry)
schedule
    The schedule dict/shelve.
schedules_equal (old_schedules, new_schedules)
send_task (*args, **kwargs)
set_schedule (schedule)
setup_schedule ()
should_sync ()
sync ()

sync_every = 180
 How often to sync the schedule (3 minutes by default)

sync_every_tasks = None
 How many tasks can be called before a sync is forced.
tick (event_t=<class 'celerybeat.event_t'>, min=<built-in function min>, heappop=<built-in function heappop>, heappush=<built-in function heappush>)
Run a tick - one iteration of the scheduler.

Returns preferred delay in seconds for next call.
Return type float

update_from_dict (dict_)

class celery.beat.PersistentScheduler (*args, **kwargs)
 Scheduler backed by shelve database.
close ()
get_schedule ()
info

known_suffixes = ('', '.db', '.dat', '.bak', '.dir')
persistence = <module 'shelve' from '/home/docs/.pyenv/versions/3.7.3/lib/python3.7/shelve'>
schedule
set_schedule (schedule)
setup_schedule ()
sync ()

class celery.beat.Service (app, max_interval=None, schedule_filename=None, scheduler_cls=None)
 Celery periodic task service.
get_scheduler (lazy=False, extension_namespace='celery.beat_schedulers')
scheduler

scheduler_cls
 alias of PersistentScheduler

start (embedded_process=False)
stop (wait=False)
sync ()
**celery.beat.EmbeddedService** *(app, max_interval=None, **kwargs)*  
Return embedded clock service.

**Parameters**  
**thread** *(bool)* – Run threaded instead of as a separate process. Uses *multiprocessing* by default, if available.

### 3.11.44 celery.apps.worker

Worker command-line program.

This module is the ‘program-version’ of *celery.worker*.

It does everything necessary to run that module as an actual application, like installing signal handlers, platform tweaks, and so on.

**class celery.apps.worker.Worker** *(app=None, hostname=None, **kwargs)*  
Worker as a program.

- **emit_banner** *
- **extra_info** *
- **install_platform_tweaks** *(worker)*  
Install platform specific tweaks and workarounds.

- **macOS_proxy_detection_workaround** *
  See https://github.com/celery/celery/issues#issue/161.

- **on_after_init** *(purge=False, no_color=None, redirect_stdouts=None, redirect_stdouts_level=None, **kwargs)*  
- **on_before_init** *(quiet=False, **kwargs)*  
- **on_consumer_ready** *(consumer)*  
- **on_init_blueprint** *
- **on_start** *
- **purge_messages** *
- **set_process_status** *(info)*  
- **setup_logging** *(colorize=None)*  
- **startup_info** *(artlines=True)*  
- **tasklist** *(include_builtins=True, sep='\n', int_='celery: ')*

### 3.11.45 celery.apps.beat

Beat command-line program.

This module is the ‘program-version’ of *celery.beat*.

It does everything necessary to run that module as an actual application, like installing signal handlers and so on.

**class celery.apps.beat.Beat** *(max_interval=None, app=None, socket_timeout=30, pidfile=None, no_color=None, loglevel='WARN', logfile=None, schedule=None, scheduler=None, scheduler_cls=None, redirect_stdouts=None, redirect_stdouts_level=None, **kwargs)*  
Beat as a service.
class Service (app, max_interval=None, schedule_filename=None, scheduler_cls=None)
Celery periodic task service.

get_scheduler (lazy=False, extension_namespace='celery.beat_schedulers')
scheduler
scheduler_cls
   alias of PersistentScheduler
start (embedded_process=False)
stop (wait=False)
sync()

app = None
banner (service)
init_loader()

install_sync_handler (service)
   Install a SIGTERM + SIGINT handler saving the schedule.
run()
set_process_title()
setup_logging (colorize=None)
start_scheduler()
startup_info (service)

3.11.46 celery.apps.multi
Start/stop/manage workers.

class celery.apps.multi.Cluster (nodes, cmd=None, env=None, on_stopping_preamble=None, on_send_signal=None, on_still_waiting_for=None, on_still_waiting_progress=None, on_still_waiting_end=None, on_node_start=None, on_node_restart=None, on_node_shutdown_ok=None, on_node_status=None, on_node_signal=None, on_node_signal_dead=None, on_node_down=None, on_child_spawn=None, on_child_signalled=None, on_child_failure=None)
   Represent a cluster of workers.

data
find (name)
getpids (on_down=None)
kill()
restart (sig=<Signals.SIGTERM: 15>)
send_all (sig)
shutdown_nodes (nodes, sig=<Signals.SIGTERM: 15>, retry=None)
start()
start_node (node)
stop (retry=None, callback=None, sig=<Signals.SIGTERM: 15>)

stopwait (retry=2, callback=None, sig=<Signals.SIGTERM: 15>)

class celery.apps.multi.Node (name, cmd=None, append=None, options=None, extra_args=None)

Represents a node in a cluster.

alive()

argv_with_executable

executable

classmethod from_kwargs (name, **kwargs)

gopt (*alt)

handle_process_exit (retcode, on_signalled=None, on_failure=None)

pidfile

prepare_argv (argv, path)

send (sig, on_error=None)

start (env=None, **kwargs)

3.11.47 celery.worker

Worker implementation.

class celery.worker.WorkController (app=None, hostname=None, **kwargs)

Unmanaged worker instance.

class Blueprint (steps=None, name=None, on_start=None, on_close=None, on_stopped=None)

Worker bootstep blueprint.

    default_steps = {'celery.worker.autoscale:WorkerComponent', 'celery.worker.components:Beat', ...

        'celery.worker.components:Pool', 'celery.worker.components:StateDB', 'celery.worker.components:Timer'}

name = 'Worker'

app = None

blueprint = None

exitcode = None

contains the exit code if a SystemExit event is handled.

info()

on_after_init (**kwargs)

on_before_init (**kwargs)

on_close()

on_consumer_ready (consumer)

on_init_blueprint ()

on_start()

setup_queues(include, exclude=None)
should_use_eventloop()
signal_consumer_close()
start()
state
stats()
stop(in_sighandler=False, exitcode=None)
Graceful shutdown of the worker server.
terminate(in_sighandler=False)
Not so graceful shutdown of the worker server.

3.11.48 celery.worker.request

Task request.

This module defines the Request class, that specifies how tasks are executed.

class celery.worker.request.Request (message, on_ack=<function noop>, hostname=None, eventer=None, app=None, connection_errors=None, request_dict=None, task=None, on_reject=<function noop>, body=None, headers=None, decoded=False, utc=True, maybe_make_aware=<function maybe_make_aware>, maybe_iso8601=<function maybe_iso8601>, **opts)

A request for task execution.

acknowledge ()
    Acknowledge task.
acknowledged = False
app
args
argsrepr
body
chord
connection_errors
content_encoding
content_type
correlation_id
delivery_info
errbacks
eta
eventer
execute(loglevel=None, logfile=None)
    Execute the task in a `trace_task()`.

Parameters

    • loglevel (int) – The loglevel used by the task.
    • logfile (str) – The logfile used by the task.

execute_using_pool(pool, **kwargs)
    Used by the worker to send this task to the pool.

    Parameters pool (TaskPool) – The execution pool used to execute this request.

    Raises celery.exceptions.TaskRevokedError – if the task was revoked.

expires
group
hostname
humaninfo()
id
info(safe=False)
kwargs
kwargsrepr
maybe_expire()
    If expired, mark the task as revoked.
message
name
on_accepted(pid, time_accepted)
    Handler called when task is accepted by worker pool.
on_ack

on_failure(exc_info, send_failed_event=True, return_ok=False)
    Handler called if the task raised an exception.

on_reject

on_retry(exc_info)
    Handler called if the task should be retried.

on_success(failed retval runtime, **kwargs)
    Handler called if the task was successfully processed.

on_timeout(soft, timeout)
    Handler called if the task times out.

parent_id

reject(requeue=False)

reply_to

request_dict

revoked()
    If revoked, skip task and mark state.

root_id

send_event(type, **fields)

store_errors

tzlocal

utc

worker_pid = None

3.11.49 celery.worker.state

Internal worker state (global).

This includes the currently active and reserved tasks, statistics, and revoked tasks.

celery.worker.state.SOFTWARE_INFO = {'sw_ident': 'py-celery', 'sw_sys': 'Linux', 'sw_ver': '4.4.0'}

Worker software/platform information.

celery.worker.state.reserved_requests = <weakrefset.WeakSet object>
    set of all reserved Request's.

celery.worker.state.active_requests = <weakrefset.WeakSet object>
    set of currently active Request's.
```
celery.worker.state.total_count = {}
count of tasks accepted by the worker, sorted by type.

celery.worker.state.revoked = <LimitedSet(0): maxlen=50000, expires=10800, minlen=0>
the list of currently revoked tasks. Persistent if statedb set.

celery.worker.state.task_reserved(request, add_request=<method-wrapper '__setitem__' of
dict object>, add_reserved_request=<bound method WeakSet.add of <_weakrefset.WeakSet object>>)
Update global state when a task has been reserved.

celery.worker.state.maybe_shutdown()
Shutdown if flags have been set.

celery.worker.state.task_accepted(request, _all_total_count=None,
add_active_request=<bound method WeakSet.add of <_weakrefset.WeakSet object>>,
add_to_total_count=<bound method Counter.update of Counter()>)
Update global state when a task has been accepted.

celery.worker.state.task_ready(request, remove_request=<built-in method pop of dict
object>, discard_active_request=<bound method WeakSet.discard of <_weakrefset.WeakSet object>>,
discard_reserved_request=<bound method WeakSet.discard of <_weakrefset.WeakSet object>>)
Update global state when a task is ready.

class celery.worker.state.Persistent(state, filename, clock=None)
Stores worker state between restarts.
This is the persistent data stored by the worker when celery worker --statedb is enabled.
Currently only stores revoked task id’s.

close()
compress()
Returns a bytes object containing compressed data.
data Binary data to be compressed.
level Compression level, in 0-9 or -1.
db
decompress()
Returns a bytes object containing the uncompressed data.
data Compressed data.
wbits The window buffer size and container format.
bufsize The initial output buffer size.
merge()
open()
protocol = 2
save()
storage = <module 'shelve' from '/home/docs/.pyenv/versions/3.7.3/lib/python3.7/shelve
sync()
```
3.11.50 celery.worker.strategy

Task execution strategy (optimization).

celery.worker.strategy.default(task, app, consumer, info=<bound method Logger.info of <Logger celery.worker.strategy (WARNING)>>, error=<bound method Logger.error of <Logger celery.worker.strategy (WARNING)>>, task_reserved=<function task_reserved>, to_system_tz=<bound method _Zone.to_system of <celery.utils.time._Zone object>>, bytes=<class 'bytes'>, buffer_t=<class 'vine.five.buffer_t'>, proto1_to_proto2=<function proto1_to_proto2>)

Default task execution strategy.

**Note:** Strategies are here as an optimization, so sadly it’s not very easy to override.

3.11.51 celery.worker.consumer

Worker consumer.

class celery.worker.consumer.Consumer(on_task_request=None, init_callback=<function noop>, hostname=None, pool=None, app=None, timer=None, controller=None, hub=None, amqheartbeat=None, worker_options=None, disable_rate_limits=False, initial_prefetch_count=2, prefetch_multiplier=1, **kwargs)

Consumer blueprint.

class Blueprint(steps=None, name=None, on_start=None, on_close=None, on_stopped=None)

Consumer blueprint.

    default_steps = ['celery.worker.consumer.connection:Connection', 'celery.worker.consumer.mingle:Mingle', ...

name = 'Consumer'

shutdown(parent)

**Strategies**

alias of builtins.dict

add_task_queue(queue, exchange=None, exchange_type=None, routing_key=None, **options)

apply_eta_task(task)

Method called by the timer to apply a task with an ETA/countdown.

bucket_for_task(type)

call_soon(p, *args, **kwargs)

cancel_task_queue(queue)

connect()

Establish the broker connection used for consuming tasks.

Retries establishing the connection if the broker_connection_retry setting is enabled

connection_for_read(heartbeat=None)

connection_for_write(heartbeat=None)
**create_task_handler** *(promise=<class 'vine.promises.promise'>)*

**ensure_connected**(conn)

**init_callback** = None

Optional callback called the first time the worker is ready to receive tasks.

**loop_args**()

**on_close**()

**on_connection_error_after_connected**(exc)

**on_connection_error_before_connected**(exc)

**on_decode_error**(message, exc)

Callback called if an error occurs while decoding a message.

Simply logs the error and acknowledges the message so it doesn’t enter a loop.

Parameters

- **message** *(kombu.Message)* – The message received.
- **exc** *(Exception)* – The exception being handled.

**on_invalid_task**(body, message, exc)

**on_ready**()

**on_send_event_buffered**()

**on_unknown_message**(body, message)

**on_unknown_task**(body, message, exc)

**perform_pending_operations**()

**pool** = None

The current worker pool instance.

**register_with_event_loop**(hub)

**reset_rate_limits**()

**restart_count** = -1

**shutdown**()

**start**()

**stop**()

**timer** = None

A timer used for high-priority internal tasks, such as sending heartbeats.

**update_strategies**()

**class celery.worker.consumer.Agent**(c, **kwargs)**

Agent starts cell actors.

**conditional** = True

**create**(c)

Create the step.

**name** = 'celery.worker.consumer.agent.Agent'

**requires** = (step:celery.worker.consumer.connection.Connection{()},)
class celery.worker.consumer.Connection(c, **kwargs)
Service managing the consumer broker connection.

info(c)
name = 'celery.worker.consumer.connection.Connection'
shutdown(c)
start(c)

class celery.worker.consumer.Control(c, **kwargs)
Remote control command service.

include_if(c)
    Return true if bootstep should be included.
    You can define this as an optional predicate that decides whether this step should be created.

name = 'celery.worker.consumer.control.Control'

class celery.worker.consumer.Events(c, task_events=True, without_heartbeat=False, without_gossip=False, **kwargs)
Service used for sending monitoring events.

name = 'celery.worker.consumer.events.Events'
requires = (step:celery.worker.consumer.connection.Connection{()},)
shutdown(c)
start(c)
stop(c)

class celery.worker.consumer.Gossip(c, without_gossip=False, interval=5.0, heartbeat_interval=2.0, **kwargs)
Bootstep consuming events from other workers.
This keeps the logical clock value up to date.

call_task(task)
compatible_transport(app)
compatible_transports = {'amqp', 'redis'}
election(id, topic, action=None)
get_consumers(channel)
label = 'Gossip'
name = 'celery.worker.consumer.gossip.Gossip'
on_elect(event)
on_elect_ack(event)
on_message(prepare, message)
on_node_join(worker)
on_node_leave(worker)
on_node_lost(worker)
periodic()
```
register_timer()

start (c)

class celery.worker.consumer.Heart (c, without_heartbeat=False, heartbeat_interval=None, **kwargs)

  Bootstrap sending event heartbeats.

  This service sends a worker-heartbeat message every n seconds.

  **Note:** Not to be confused with AMQP protocol level heartbeats.

  name = 'celery.worker.consumer.heart.Heart'

  requires = (step:celery.worker.consumer.events.Events{(step:celery.worker.consumer.connection.Connection{()},)},)

  shutdown (c)

  start (c)

  stop (c)

class celery.worker.consumer.Mingle (c, without_mingle=False, **kwargs)

  Bootstrap syncing state with neighbor workers.

  At startup, or upon consumer restart, this will:

  • Sync logical clocks.

  • Sync revoked tasks.

  compatible_transport (app)

  compatible_transports = {'amqp', 'redis'}

  label = 'Mingle'

  name = 'celery.worker.consumer.mingle.Mingle'

  on_clock_event (c, clock)

  on_node_reply (c, nodename, reply)

  on_revoked_received (c, revoked)

  requires = (step:celery.worker.consumer.events.Events{(step:celery.worker.consumer.connection.Connection{()},)},)

  send_hello (c)

  start (c)

  sync (c)

  sync_with_node (c, clock=None, revoked=None, **kwargs)

class celery.worker.consumer.Tasks (c, **kwargs)

  Bootstrap starting the task message consumer.

  info (c)

  Return task consumer info.

  name = 'celery.worker.consumer.tasks.Tasks'

```
shutdown \(c\)
Shutdown task consumer.

start \(c\)
Start task consumer.

stop \(c\)
Stop task consumer.

### 3.11.52 celery.worker.consumer.agent

Celery + cell integration.

class celery.worker.consumer.agent.Agent \((c, **kwargs)\)
Agent starts cell actors.

conditional = True

create \(c\)
Create the step.

name = 'celery.worker.consumer.agent.Agent'
requires = (step:celery.worker.consumer.connection.Connection{()},)

### 3.11.53 celery.worker.consumer.connection

Consumer Broker Connection Bootstep.

class celery.worker.consumer.connection.Connection \((c, **kwargs)\)
Service managing the consumer broker connection.

info \(c\)

name = 'celery.worker.consumer.connection.Connection'
shutdown \(c\)
start \(c\)

### 3.11.54 celery.worker.consumer.consumer

Worker Consumer Blueprint.

This module contains the components responsible for consuming messages from the broker, processing the messages and keeping the broker connections up and running.

class celery.worker.consumer.consumer.Consumer \((on_task_request, init_callback=<function noop>, hostname=None, pool=None, app=None, timer=None, controller=None, hub=None, amqheartbeat=None, worker_options=None, disable_rate_limits=False, initial_prefetch_count=2, prefetch_multiplier=1, **kwargs)\)

Consumer blueprint.
class Blueprint(steps=None, name=None, on_start=None, on_close=None, on_stopped=None)
    Consumer blueprint.
    
    default_steps = ['celery.worker.consumer.connection:Connection', 'celery.worker.consumer.mingle:Mingle', ...
    name = 'Consumer'
    shutdown(parent)

Strategies
    alias of builtins.dict

add_task_queue(queue, exchange=None, exchange_type=None, routing_key=None, **options)

apply_eta_task(task)
    Method called by the timer to apply a task with an ETA/countdown.

bucket_for_task(type)

call_soon(p, *args, **kwargs)

cancel_task_queue(queue)

connect()
    Establish the broker connection used for consuming tasks.
    Retries establishing the connection if the broker_connection_retry setting is enabled

connection_for_read(heartbeat=None)

connection_for_write(heartbeat=None)

create_task_handler(promise=<class 'vine.promises.promise'>)

ensure_connected(conn)

init_callback = None
    Optional callback called the first time the worker is ready to receive tasks.

loop_args()

on_close()

on_connection_error_after_connected(exc)

on_connection_error_before_connected(exc)

on_decode_error(message, exc)
    Callback called if an error occurs while decoding a message.
    Simply logs the error and acknowledges the message so it doesn’t enter a loop.

    Parameters
    
    • message(kombu.Message) – The message received.
    • exc(Exception) – The exception being handled.

on_invalid_task(body, message, exc)

on_ready()

on_send_event_buffered()

on_unknown_message(body, message)

on_unknown_task(body, message, exc)

perform_pending_operations()
pool = None

The current worker pool instance.

register_with_event_loop(hub)
reset_rate_limits()
restart_count = -1
shutdown()
start()
stop()
timer = None

A timer used for high-priority internal tasks, such as sending heartbeats.

update_strategies()

class celery.worker.consumer.consumer.Evloop(parent, **kwargs)

Event loop service.

Note: This is always started last.

label = 'event loop'
last = True
name = 'celery.worker.consumer.consumer.Evloop'

patch_all(c)
start(c)
celery.worker.consumer.consumer.dump_body(m, body)

Format message body for debugging purposes.

3.11.55 celery.worker.consumer.control

Worker Remote Control Bootstep.

Control -> celery.worker.pidbox -> kombu.pidbox.

The actual commands are implemented in celery.worker.control.

class celery.worker.consumer.control.Control(c, **kwargs)
Remote control command service.

include_if(c)

Return true if bootstep should be included.

You can define this as an optional predicate that decides whether this step should be created.

name = 'celery.worker.consumer.control.Control'

3.11.56 celery.worker.consumer.events

Worker Event Dispatcher Bootstep.

Events -> celery.events.EventDispatcher.

class celery.worker.consumer.events.Events(c, task_events=True,
 without_heartbeat=False, without_gossip=False,
 **kwargs)

    Service used for sending monitoring events.
    name = 'celery.worker.consumer.events.Events'
    requires = (step:celery.worker.consumer.connection.Connection{()},)
    shutdown(c)
    start(c)
    stop(c)

3.11.57 celery.worker.consumer.gossip

Worker <-> Worker communication Bootstep.

class celery.worker.consumer.gossip.Gossip(c, without_gossip=False,
 interval=5.0, heartbeat_interval=2.0, **kwargs)

    Bootstep consuming events from other workers.
    This keeps the logical clock value up to date.
    call_task(task)
    compatible_transport(app)
    compatible_transports = {'amqp', 'redis'}
    election(id, topic, action=None)
    get_consumers(channel)
    label = 'Gossip'
    name = 'celery.worker.consumer.gossip.Gossip'
    on_elect(event)
    on_elect_ack(event)
    on_message(prepare, message)
    on_node_join(worker)
    on_node_leave(worker)
    on_node_lost(worker)
    periodic()
    register_timer()
    requires = (step:celery.worker.consumer.mingle.Mingle{(step:
     celery.worker.consumer.events.Events{(step:celery.worker.consumer.connection.Connection{()},)},)},)
    start(c)
3.11.58 celery.worker.consumer.heart

Worker Event Heartbeat Bootstrap.

```python
class celery.worker.consumer.heart.Heart(c, without_heartbeat=False, heartbeat_interval=None, **kwargs)
```

Bootstep sending event heartbeats.

This service sends a `worker-heartbeat` message every n seconds.

**Note:** Not to be confused with AMQP protocol level heartbeats.

```python
name = 'celery.worker.consumer.heart.Heart'
requires = (step:celery.worker.consumer.events.Events{(step:celery.worker.consumer.connection.Connection{()},)},)
shutdown(c)
start(c)
stop(c)
```

3.11.59 celery.worker.consumer.mingle

Worker <-> Worker Sync at startup (Bootstrap).

```python
class celery.worker.consumer.mingle.Mingle(c, without_mingle=False, **kwargs)
```

Bootstep syncing state with neighbor workers.

At startup, or upon consumer restart, this will:

- Sync logical clocks.
- Sync revoked tasks.

```python
compatible_transport(app)
compatible_transports = {'amqp', 'redis'}
label = 'Mingle'
name = 'celery.worker.consumer.mingle.Mingle'
on_clock_event(c, clock)
on_node_reply(c, nodename, reply)
on_revoked_received(c, revoked)
requires = (step:celery.worker.consumer.events.Events{(step:celery.worker.consumer.connection.Connection{()},)},)
send_hello(c)
start(c)
sync(c)
sync_with_node(c, clock=None, revoked=None, **kwargs)
```
3.11.60 `celery.worker.consumer.tasks`

Worker Task Consumer Bootstep.

```python
class celery.worker.consumer.tasks.Tasks(c, **kwargs):
    Bootstep starting the task message consumer.
    info(c)
        Return task consumer info.
    name = 'celery.worker.consumer.tasks.Tasks'
    shutdown(c)
        Shutdown task consumer.
    start(c)
        Start task consumer.
    stop(c)
        Stop task consumer.
```

3.11.61 `celery.worker.worker`

WorkController can be used to instantiate in-process workers.

The command-line interface for the worker is in `celery.bin.worker`, while the worker program is in `celery.apps.worker`.

The worker program is responsible for adding signal handlers, setting up logging, etc. This is a bare-bones worker without global side-effects (i.e., except for the global state stored in `celery.worker.state`).

The worker consists of several components, all managed by bootsteps (mod:`celery.bootsteps`).

```python
class celery.worker.worker.WorkController(app=None, hostname=None, **kwargs):
    Unmanaged worker instance.
    class Blueprint(steps=None, name=None, on_start=None, on_close=None, on_stopped=None):
        Worker bootstep blueprint.
        default_steps = {'celery.worker.autoscale:WorkerComponent', 'celery.worker.components:Beat', ... 'celery.worker.components:Pool', 'celery.worker.components:StateDB', 'celery.worker.components:Timer'}
        name = 'Worker'
    app = None
    blueprint = None
    exitcode = None
        contains the exit code if a SystemExit event is handled.
    info()
    on_after_init(**kwargs)
    on_before_init(**kwargs)
    on_close()
    on_consumer_ready(consumer)
    on_init_blueprint()
    on_start()
```
on_stopped()

pidlock = None

pool = None

prepare_args(**kwargs)

register_with_event_loop(hub)

reload(modules=None, reload=False, reloader=None)

rusage()

semaphore = None

setup_defaults(concurrency=None, loglevel='WARN', logfile=None, task_events=None, pool=None, consumer_cls=None, timer_cls=None, timer_precision=None, autoscaler_cls=None, pool_putlocks=None, pool_restarts=None, optimization=None, O=None, statedb=None, time_limit=None, soft_time_limit=None, scheduler=None, pool_cls=None, state_db=None, task_time_limit=None, task_soft_time_limit=None, scheduler_cls=None, schedule_filename=None, max_tasks_per_child=None, prefetch_multiplier=None, disable_rate_limits=None, worker_lost_wait=None, max_memory_per_child=None, **kw)

setup_includes(includes)

setup_instance(queues=None, ready_callback=None, pidfile=None, include=None, use_eventloop=None, exclude_queues=None, **kwargs)

setup_queues(include, exclude=None)

should_use_eventloop()

signal_consumer_close()

start()

state

stats()

stop(in_sighandler=False, exitcode=None)

Graceful shutdown of the worker server.

terminate(in_sighandler=False)

Not so graceful shutdown of the worker server.

3.11.62 celery.bin.base

Base command-line interface.

exception celery.bin.base.Error(reason, status=None)

Exception raised by commands.

status = 1

exception celery.bin.base.UsageError(reason, status=None)

Exception raised for malformed arguments.

status = 64

class celery.bin.base.Extensions(namespace, register)

Loads extensions from setuptools entrypoints.
add(cls, name)

load()

class celery.bin.base.Command(app=None, get_app=None, no_color=False, std-
out=None, stderr=None, quiet=False, on_error=None, on_usage_error=None)

Base class for command-line applications.

Parameters

• app (Celery) – The app to use.

• get_app (Callable) – Function returning the current app when no app provided.

exception Error (reason, status=None)

Exception raised by commands.

status = 1

Parser

alias of argparse.ArgumentParser

exception UsageError (reason, status=None)

Exception raised for malformed arguments.

status = 64

add_append_opt (acc, opt, value)

add_arguments (parser)

add_compat_options (parser, options)

add_preload_arguments (parser)

args = ''

Arg list used in help.

args_name = 'args'

Name of argparse option used for parsing positional args.

ask (q, choices, default=None)

Prompt user to choose from a tuple of string values.

If a default is not specified the question will be repeated until the user gives a valid choice.

Matching is case insensitive.

Parameters

• q (str) – the question to ask (don’t include questionark)

• choice (Tuple[str]) – tuple of possible choices, must be lowercase.

• default (Any) – Default value if any.

check_args (args)

colored

create_parser (prog_name, command=None)

description = ''

Text to print in –help before option list.

die (msg, status=1)

doc = None
early_version(\textit{argv})

\textbf{enable_config_from_cmdline} = False

Enable if the application should support config from the cmdline.

epilog = None

Text to print at end of –help

error(s)

\textbf{execute_from_commandline}(\textit{argv=None})

Execute application from command-line.

\begin{itemize}
  \item \textbf{argv} (\textit{List [str]}) – The list of command-line arguments. Defaults to \textit{sys.argv}.
\end{itemize}

expanduser(\textit{value})

\textbf{find_app}(\textit{app})

\textbf{get_cls_by_name}(\textit{name}, \textit{imp=<function import_from_cwd>})

\textbf{get_options}()

\textbf{handle_argv}(\textit{prog_name}, \textit{argv}, \textit{command=None})

Parse arguments from argv and dispatch to \textit{run}().

\begin{itemize}
  \item \textbf{prog_name} (\textit{str}) – The program name (\textit{argv}[0]).
  \item \textbf{argv} (\textit{List [str]}) – Rest of command-line arguments.
\end{itemize}

\textbf{host_format}(\textit{s}, **\textit{extra})

\textbf{leaf} = True

Set to true if this command doesn’t have sub-commands

\textbf{maybe_patch_concurrency}(\textit{argv=None})

namespace = None

Default configuration name-space.

\textbf{no_color}

\textbf{node_format}(\textit{s}, \textit{nodename}, **\textit{extra})

\textbf{on_concurrency_setup}()

\textbf{on_error}(\textit{exc})

\textbf{on_usage_error}(\textit{exc})

\textbf{option_list} = None

List of options (without preload options).

\textbf{out}(\textit{s}, \textit{fh=None})

\textbf{parse_doc}(\textit{doc})
parse_options *(prog_name, arguments, command=None)*
    Parse the available options.

parse_preload_options *(args)*

prepare_args *(options, args)*

prepare_arguments *(parser)*

prepare_parser *(parser)*

pretty *(n)*

pretty_dict_ok_error *(n)*

pretty_list *(n)*

process_cmdline_config *(argv)*

prog_name = 'celery'

respects_app_option = True

run *(*args, **options)*

run_from_argv *(prog_name, argv=None, command=None)*

say_chat *(direction, title, body=’’)*

say_remote_command_reply *(replies)*

setup_app_from_commandline *(argv)*

show_body = True

show_reply = True

supports_args = True
    If false the parser will raise an exception if positional args are provided.

symbol_by_name *(name, imp=<function import_from_cwd>)*

usage *(command)*

verify_args *(given, _index=0)*

version = '4.4.0 (cliffs)'
    Application version.

with_pool_option *(argv)*
    Return tuple of (short_opts, long_opts).
    Returns only if the command supports a pool argument, and used to monkey patch eventlet/gevent environments as early as possible.

**Example**

```python
>>> has_pool_option = (['-P'], ['--pool'])
```

class celery.bin.base.Option (*opts, **attrs)*

**Instance attributes:** _short_opts : [string]_ _long_opts : [string]_

ACTIONS = ('store', 'store_const', 'store_true', 'store_false', 'append', 'append_const', 'count', 'callback', 'help', 'version')

ALWAYS_TYPED_ACTIONS = ('store', 'append')

ATTRS = ['action', 'type', 'dest', 'default', 'nargs', 'const', 'choices', 'callback', 'callback_args', 'callback_kwargs', 'help', 'metavar']

CHECK_METHODS = [<function Option._check_action>, <function Option._check_type>, <function Option._check_choice>, <function Option._check_dest>, <function Option._check_const>, <function Option._check_nargs>, <function Option._check_callback>]

CONST_ACTIONS = ('store_const', 'append_const')

STORE_ACTIONS = ('store', 'store_const', 'store_true', 'store_false', 'append', 'append_const', 'count')

TYPED_ACTIONS = ('store', 'append', 'callback')

TYPES = ('string', 'int', 'long', 'float', 'complex', 'choice')

TYPE_CHECKER = {'choice': <function check_choice>, 'complex': <function check_builtin>, 'float': <function check_builtin>, 'int': <function check_builtin>, 'long': <function check_builtin>}

check_value (opt, value)
convert_value (opt, value)
get_opt_string ()
process (opt, value, values, parser)
take_action (action, dest, opt, value, values, parser)
takes_value ()
celery.bin.base.daemon_options (parser, default_pidfile=None, default_logfile=None)
Add daemon options to argparse parser.

3.11.63 celery.bin.celery

- Preload Options
- Daemon Options
  - celery inspect
  - celery control
  - celery migrate
  - celery upgrade
  - celery shell
  - celery result
  - celery purge
  - celery call

The `celery` umbrella command.

Preload Options

These options are supported by all commands, and usually parsed before command-specific arguments.

-A, --app
   app instance to use (e.g., `module.attr_name`)
Celery Documentation, Release 4.4.0

-b, --broker
    URL to broker. default is amqp://guest@localhost//

--loader
    name of custom loader class to use.

--config
    Name of the configuration module

-C, --no-color
    Disable colors in output.

-q, --quiet
    Give less verbose output (behavior depends on the sub command).

--help
    Show help and exit.

Daemon Options

These options are supported by commands that can detach into the background (daemon). They will be present in any command that also has a --detach option.

-f, --logfile
    Path to log file. If no logfile is specified, stderr is used.

--pidfile
    Optional file used to store the process pid.
    The program won’t start if this file already exists and the pid is still alive.

--uid
    User id, or user name of the user to run as after detaching.

--gid
    Group id, or group name of the main group to change to after detaching.

--umask
    Effective umask (in octal) of the process after detaching. Inherits the umask of the parent process by default.

--workdir
    Optional directory to change to after detaching.

--executable
    Executable to use for the detached process.

celery inspect

-t, --timeout
    Timeout in seconds (float) waiting for reply

-d, --destination
    Comma separated list of destination node names.

-j, --json
    Use json as output format.
celery control

- `t`, `--timeout`
  Timeout in seconds (float) waiting for reply

- `d`, `--destination`
  Comma separated list of destination node names.

- `j`, `--json`
  Use json as output format.

celery migrate

- `n`, `--limit`
  Number of tasks to consume (int).

- `t`, `--timeout`
  Timeout in seconds (float) waiting for tasks.

- `a`, `--ack-messages`
  Ack messages from source broker.

- `T`, `--tasks`
  List of task names to filter on.

- `Q`, `--queues`
  List of queues to migrate.

- `F`, `--forever`
  Continually migrate tasks until killed.

celery upgrade

- `--django`
  Upgrade a Django project.

- `--compat`
  Maintain backwards compatibility.

- `--no-backup`
  Don’t backup original files.

celery shell

- `I`, `--ipython`
  Force iPython implementation.

- `B`, `--bpython`
  Force bpython implementation.

- `P`, `--python`
  Force default Python shell.

- `T`, `--without-tasks`
  Don’t add tasks to locals.

- `--eventlet`
  Use eventlet monkey patches.
--gevent
Use gevent monkey patches.

celery result
-t, --task
Name of task (if custom backend).
--traceback
Show traceback if any.

celery purge
-f, --force
Don’t prompt for verification before deleting messages (DANGEROUS)

celery call
-a, --args
Positional arguments (json format).
-k, --kwargs
Keyword arguments (json format).
--eta
Scheduled time in ISO-8601 format.
--countdown
ETA in seconds from now (float/int).
--expires
Expiry time in float/int seconds, or a ISO-8601 date.
--serializer
Specify serializer to use (default is json).
--queue
Destination queue.
--exchange
Destination exchange (defaults to the queue exchange).
--routing-key
Destination routing key (defaults to the queue routing key).

class celery.bin.celery.CeleryCommand (app=None, get_app=None, no_color=False, stdout=None, stderr=None, quiet=False, on_error=None, on_usage_error=None)
Base class for commands.

3.11. API Reference
Parameters **argv** *(List[str]*) – The list of command-line arguments. Defaults to `sys.argv`.

**ext_fmt** = '{self.namespace}.commands'

```
classmethod get_command_info(command, indent=0, color=None, colored=None, app=None)
```

**handle_argv**(prog_name, argv, **kwargs)

Parse arguments from argv and dispatch to `run()`.

**Warning:** Exits with an error message if `supports_args` is disabled and argv contains positional arguments.

Parameters

- **prog_name** *(str)* – The program name (argv[0]).
- **argv** *(List[str]*) – Rest of command-line arguments.

```
classmethod list_commands(indent=0, colored=None, app=None)
```

**load_extension_commands**()

**namespace** = 'celery'

**on_concurrency_setup**()

**on_usage_error**(exc, command=None)

**prepare_prog_name**(name)

**prog_name** = 'celery'

```
classmethod register_command(fun, name=None)
```

**with_pool_option**(argv)

Return tuple of *(short_opts, long_opts)*.

Returns only if the command supports a pool argument, and used to monkey patch eventlet/gevent environments as early as possible.

**Example**

```
>>> has_pool_option = (('-P',), ['--pool'])
```

celery.bin.celery.main*(argv=None)*

Start celery umbrella command.

**3.11.64** celery.bin.worker

Program used to start a Celery worker instance.

The **celery worker** command (previously known as celeryd)

See also:

See Preload Options.
Celery Documentation, Release 4.4.0

- **c** or **--concurrency**
  Number of child processes processing the queue. The default is the number of CPUs available on your system.

- **P** or **--pool**
  Pool implementation:
  - prefork (default), eventlet, gevent, threads or solo.

- **n** or **--hostname**
  Set custom hostname (e.g., ‘w1@%h’). Expands: %h (hostname), %n (name) and %d, (domain).

- **B** or **--beat**
  Also run the celery beat periodic task scheduler. Please note that there must only be one instance of this service.

  **Note:** -B is meant to be used for development purposes. For production environment, you need to start celery beat separately.

- **Q** or **--queues**
  List of queues to enable for this worker, separated by comma. By default all configured queues are enabled.
  Example: -Q video,image

- **X** or **--exclude-queues**
  List of queues to disable for this worker, separated by comma. By default all configured queues are enabled.
  Example: -X video,image.

- **I** or **--include**
  Comma separated list of additional modules to import. Example: -I foo.tasks,bar.tasks

- **s** or **--schedule**
  Path to the schedule database if running with the -B option. Defaults to celerybeat-schedule. The extension ".db" may be appended to the filename.

- **O**
  Apply optimization profile. Supported: default, fair

  **--prefetch-multiplier**
  Set custom prefetch multiplier value for this worker instance.

  **--scheduler**
  Scheduler class to use. Default is celery.beat.PersistentScheduler

- **S** or **--statedb**
  Path to the state database. The extension `.db` may be appended to the filename. Default: {default}

- **E** or **--task-events**
  Send task-related events that can be captured by monitors like celery events, celerymon, and others.

  **--without-gossip**
  Don’t subscribe to other workers events.

  **--without-mingle**
  Don’t synchronize with other workers at start-up.

  **--without-heartbeat**
  Don’t send event heartbeats.

  **--heartbeat-interval**
  Interval in seconds at which to send worker heartbeat.
--purge
Purges all waiting tasks before the daemon is started. WARNING: This is unrecoverable, and the tasks will be deleted from the messaging server.

--time-limit
Enables a hard time limit (in seconds int/float) for tasks.

--soft-time-limit
Enables a soft time limit (in seconds int/float) for tasks.

--max-tasks-per-child
Maximum number of tasks a pool worker can execute before it’s terminated and replaced by a new worker.

--max-memory-per-child
Maximum amount of resident memory, in KiB, that may be consumed by a child process before it will be replaced by a new one. If a single task causes a child process to exceed this limit, the task will be completed and the child process will be replaced afterwards. Default: no limit.

--autoscale
Enable autoscaling by providing max_concurrency, min_concurrency. Example:

```
--autoscale=10,3
```
(always keep 3 processes, but grow to 10 if necessary)

--detach
Start worker as a background process.

-f, --logfile
Path to log file. If no logfile is specified, stderr is used.

-l, --loglevel
Logging level, choose between DEBUG, INFO, WARNING, ERROR, CRITICAL, or FATAL.

--pidfile
Optional file used to store the process pid.

The program won’t start if this file already exists and the pid is still alive.

--uid
User id, or user name of the user to run as after detaching.

--gid
Group id, or group name of the main group to change to after detaching.

--umask
Effective umask(1) (in octal) of the process after detaching. Inherits the umask(1) of the parent process by default.

--workdir
Optional directory to change to after detaching.

--executable
Executable to use for the detached process.

```python
class celery.bin.worker.worker(app=None, get_app=None, no_color=False, stdout=None, stderr=None, quiet=False, on_error=None, on_usage_error=None)
```
Start worker instance.
Examples

```
$ celery worker --app=proj -l info
$ celery worker -A proj -l info -Q hipri,lopri

$ celery worker -A proj --concurrency=4
$ celery worker -A proj --concurrency=1000 -P eventlet
$ celery worker --autoscale=10,0
```

```
add_arguments (parser)

doc = 'Program used to start a Celery worker instance.

The :program:`celery worker` command (previously known as ... directory to change to after detaching.

.. cmdoption:: --executable

 Executable to use for the detached process.
'

enable_config_from_cmdline = True

maybe_detach (argv, dopts=None)

namespace = 'worker'

removed_flags = {'--force-execv', '--no-execv'}

run (hostname=None, pool_cls=None, app=None, uid=None, gid=None, loglevel=None, logfile=None, pidfile=None, statedb=None, **kwargs)

run_from_argv (prog_name, argv=None, command=None)

supports_args = False

with_pool_option (argv)

Return tuple of (short_opts, long_opts).

Returns only if the command supports a pool argument, and used to monkey patch eventlet/gevent environments as early as possible.

Example

```
>>> has_pool_option = (['-P'], ['--pool'])
```

celery.bin.worker.main (app=None)

Start worker.

3.11.65 celery.bin.beat

The celery beat command.

See also:

See  Preload Options and Daemon Options.

--detach

Detach and run in the background as a daemon.

-s, --schedule

Path to the schedule database. Defaults to celerybeat-schedule. The extension ‘.db’ may be appended to the filename. Default is {default}.

-S, --scheduler

Scheduler class to use. Default is {default}.

--max-interval

Max seconds to sleep between schedule iterations.
-f, --logfile
Path to log file. If no logfile is specified, stderr is used.

-l, --loglevel
Logging level, choose between DEBUG, INFO, WARNING, ERROR, CRITICAL, or FATAL.

--pidfile
File used to store the process pid. Defaults to celerybeat.pid.
The program won’t start if this file already exists and the pid is still alive.

--uid
User id, or user name of the user to run as after detaching.

--gid
Group id, or group name of the main group to change to after detaching.

--umask
Effective umask (in octal) of the process after detaching. Inherits the umask of the parent process by default.

--workdir
Optional directory to change to after detaching.

--executable
Executable to use for the detached process.

class celery.bin.beat.beat (app=None, get_app=None, no_color=False, stdout=None, stderr=None, quiet=False, on_error=None, on_usage_error=None)
Start the beat periodic task scheduler.

Examples

$ celery beat -l info
$ celery beat -s /var/run/celery/beat-schedule --detach
$ celery beat -S django

The last example requires the django-celery-beat extension package found on PyPI.

add_arguments (parser)

doc = "The :program:`celery beat` command.

enable_config_from_cmdline = True

run (detach=False, logfile=None, pidfile=None, uid=None, gid=None, umask=None, workdir=None, **kwargs)
supports_args = False

3.11.66 celery.bin.events

The celery events command.

See also:
See Preload Options and Daemon Options.

-d, --dump
Dump events to stdout.

-c, --camera
Take snapshots of events using this camera.
--detach
  Camera: Detach and run in the background as a daemon.

-F, --freq, --frequency
  Camera: Shutter frequency. Default is every 1.0 seconds.

-r, --maxrate
  Camera: Optional shutter rate limit (e.g., 10/m).

-l, --loglevel
  Logging level, choose between DEBUG, INFO, WARNING, ERROR, CRITICAL, or FATAL. Default is INFO.

-f, --logfile
  Path to log file. If no logfile is specified, stderr is used.

--pidfile
  Optional file used to store the process pid.
  The program won’t start if this file already exists and the pid is still alive.

--uid
  User id, or user name of the user to run as after detaching.

--gid
  Group id, or group name of the main group to change to after detaching.

--umask
  Effective umask (in octal) of the process after detaching. Inherits the umask of the parent process by default.

--workdir
  Optional directory to change to after detaching.

--executable
  Executable to use for the detached process.

class celery.bin.events.events(app=None, get_app=None, no_color=False, stdout=None, stderr=None, quiet=False, on_error=None, on_usage_error=None)

Event-stream utilities.

Notes

# - Start graphical monitor (requires curses)
$ celery events --app=proj
$ celery events -d --app=proj
# - Dump events to screen.
$ celery events -b amqp://
# - Run snapshot camera.
$ celery events -c <camera> [options]

Examples

$ celery events
$ celery events -d
$ celery events -c mod.attr -F 1.0 --detach --maxrate=100/m -l info

add_arguments(parser)

doc = "The :program:`celery events` command.

3.11.68 celery.bin.amqp

The celery amqp command.
class celery.bin.amqp.AMQPAdmin (*args, **kwargs)
The celery celery.amqp utility.
Shell
 alias of AMQShell
connect (conn=None)
note (m)
run ()
class celery.bin.amqp.AMQShell (*args, **kwargs)
AMQP API Shell.
Parameters
 • connect (Callable) – Function used to connect to the server. Must return kombu.Connection object.
• **silent** *(bool)* – If enabled, the commands won’t have annoying output not relevant when running in non-shell mode.

```
mapq = {'basic.ack': <celery.bin.amqp.Spec object>, 'basic.get': <celery.bin.amqp.Spec object>}
```

Map of AMQP API commands and their `Spec`.

```
builtins = {'EOF': 'do_exit', 'exit': 'do_exit', 'help': 'do_help'}
```

Map of built-in command names -> method names

```
chan = None
completenames (text, *ignored)
    Return all commands starting with `text`, for tab-completion.
conn = None
counter = 1
default (line)
    Called on an input line when the command prefix is not recognized.
    If this method is not overridden, it prints an error message and returns.
dispatch (cmd, arglist)
    Dispatch and execute the command.
    Look-up order is: `builtins` -> `amqp`.
display_command_help (cmd, short=False)
do_exit (*args)
    The ‘exit’ command.
do_help (*args)
    List available commands with “help” or detailed help with “help cmd”.
get_amqp_api_command (cmd, arglist)
    Get AMQP command wrapper.
    With a command name and a list of arguments, convert the arguments to Python values and find the corresponding method on the AMQP channel object.
    **Returns** of `(method, processed_args)` pairs.
    **Return type** Tuple
get_names ()
identchars = '.'
inc_counter = count(2)
needs_reconnect = False
note (m)
    Say something to the user. Disabled if `silent`.
onecmd (line)
    Parse line and execute command.
parseline (parts)
    Parse input line.
    **Returns**
    of three items: `(command_name, arglist, original_line)`
Return type  Tuple

prompt
str(object='') -> str str(bytes_or_buffer[, encoding[, errors]]) -> str

Create a new string object from the given object. If encoding or errors is specified, then the object must expose a data buffer that will be decoded using the given encoding and error handler. Otherwise, returns the result of object.__str__() (if defined) or repr(object). encoding defaults to sys.getdefaultencoding(). errors defaults to 'strict'.

prompt_fmt = '{self.counter}> '  
respond(retval)
What to do with the return value of a command.
say(m)

class celery.bin.amqp.Spec(*args,**kwargs)
    AMQP Command specification.
    Used to convert arguments to Python values and display various help and tool-tips.

Parameters
    •    args (Sequence) – see args.
    •    returns (str) – see returns.

args = None
List of arguments this command takes. Should contain (argument_name, argument_type) tuples.

coerce(index, value)
    Coerce value for argument at index.

format_arg(name, type, default_value=None)

format_response(response)
    Format the return value of this command in a human-friendly way.

format_signature()

returns = None
    Helpful human string representation of what this command returns. May be None, to signify the return type is unknown.

str_args_to_python(arglist)
    Process list of string arguments to values according to spec.

Example

>>> spec = Spec([['queue', str], ['if_unused', bool]])
>>> spec.str_args_to_python('pobox', 'true')
('pobox', True)

class celery.bin.amqp.amqp(app=None, get_app=None, no_color=False, stdout=None, stderr=None, quiet=False, on_error=None, on_usage_error=None)
    AMQP Administration Shell.
    Also works for non-AMQP transports (but not ones that store declarations in memory).
Examples

```bash
$ # start shell mode
$ celery amqp
$ # show list of commands
$ celery amqp help

$ celery amqp exchange.delete name
$ celery amqp queue.delete queue
$ celery amqp queue.delete queue yes yes
```

run(*args, **options)

### 3.11.69 celery.bin.graph

The `celery graph` command.

```python
class celery.bin.graph.graph(app=None, get_app=None, no_color=False, stdout=None, stderr=None, quiet=False, on_error=None, on_usage_error=None)
```

The `celery graph` command.

```python
def __init__(self, app=None, get_app=None, no_color=False, stdout=None, stderr=None, quiet=False, on_error=None, on_usage_error=None)
```

```python
args = '<TYPE> [arguments]\n ..... bootsteps [worker] [consumer]\n ..... workers [enumerate]
```

```python
bootsteps(*args, **kwargs)
```

```python
run(what=None, *args, **kwargs)
```

```python
workers(*args, **kwargs)
```

### 3.11.70 celery.bin.multi

Start multiple worker instances from the command-line.

Examples

```bash
$ # Single worker with explicit name and events enabled.
$ celery multi start Leslie -E

$ # Pidfiles and logfiles are stored in the current directory
$ # by default. Use --pidfile and --logfile argument to change
$ # this. The abbreviation %n will be expanded to the current
$ # node name.
$ celery multi start Leslie -E --pidfile=/var/run/celery/%n.pid
  --logfile=/var/log/celery/%nI.log

$ # You need to add the same arguments when you restart,
$ # as these aren't persisted anywhere.
$ celery multi restart Leslie -E --pidfile=/var/run/celery/%n.pid
  --logfile=/var/log/celery/%nI.log

$ # To stop the node, you need to specify the same pidfile.
$ celery multi stop Leslie --pidfile=/var/run/celery/%n.pid

$ # 3 workers, with 3 processes each
```
$ celery multi start 3 -c 3
  celery worker -n celery1@myhost -c 3
  celery worker -n celery2@myhost -c 3
  celery worker -n celery3@myhost -c 3

$ # start 3 named workers
$ celery multi start image video data -c 3
  celery worker -n image@myhost -c 3
  celery worker -n video@myhost -c 3
  celery worker -n data@myhost -c 3

$ # specify custom hostname
$ celery multi start 2 --hostname=worker.example.com -c 3
  celery worker -n celery1@worker.example.com -c 3
  celery worker -n celery2@worker.example.com -c 3

$ # specify fully qualified nodenames
$ celery multi start foo@worker.example.com bar@worker.example.com -c 3

$ # fully qualified nodenames but using the current hostname
$ celery multi start foo@%h bar@%h

$ # Advanced example starting 10 workers in the background:
$ # * Three of the workers processes the images and video queue
$ # * Two of the workers processes the data queue with loglevel DEBUG
$ # * the rest processes the default' queue.
$ celery multi start 10 -l INFO -Q:1-3 images,video -Q:4,5 data
  -Q default -L:4,5 DEBUG

$ # You can show the commands necessary to start the workers with
$ # the 'show' command:
$ celery multi show 10 -l INFO -Q:1-3 images,video -Q:4,5 data
  -Q default -L:4,5 DEBUG

$ # Additional options are added to each celery worker' command,
$ # but you can also modify the options for ranges of, or specific workers

$ # 3 workers: Two with 3 processes, and one with 10 processes.
$ celery multi start 3 -c 3 -c:1 10
  celery worker -n celery1@myhost -c 10
  celery worker -n celery2@myhost -c 3
  celery worker -n celery3@myhost -c 3

$ # can also specify options for named workers
$ celery multi start image video data -c 3 -c:image 10
  celery worker -n image@myhost -c 10
  celery worker -n video@myhost -c 3
  celery worker -n data@myhost -c 3

$ # ranges and lists of workers in options is also allowed:
$ # (-c:1-3 can also be written as -c:1,2,3)
$ celery multi start 5 -c 3 -c:1-3 10
  celery worker -n celery1@myhost -c 10
  celery worker -n celery2@myhost -c 10
  celery worker -n celery3@myhost -c 10
  celery worker -n celery4@myhost -c 3
  celery worker -n celery5@myhost -c 3

(continues on next page)
$ # lists also works with named workers
$ celery multi start foo bar baz xuzzy -c 3 -c:foo,bar,baz 10
celery worker -n foo@myhost -c 10
celery worker -n bar@myhost -c 10
celery worker -n baz@myhost -c 10
celery worker -n xuzzy@myhost -c 3

class celery.bin.multi.MultiTool (env=None, cmd=None, fh=None, stdout=None, stderr=None, **kwargs)
    The celery multi program.

    Cluster (nodes, cmd=None)

    DOWN

    FAILED

class MultiParser (cmd='celery worker', append='", prefix="", suffix="", range_prefix='celery')

class Node (name, cmd=None, append=None, options=None, extra_args=None)

3.11.71 celery.bin.call

The celery call program used to send tasks from the command-line.

class celery.bin.call.call (app=None, get_app=None, no_color=False, stdout=None, stderr=None, quiet=False, on_error=None, on_usage_error=None)

Call a task by name.

Examples

$ celery call tasks.add --args='[2, 2]'
$ celery call tasks.add --args='[2, 2]' --countdown=10

add_arguments (parser)
3.11.72 celery.bin.control

The celery control, inspect and status programs.

```python
class celery.bin.control.control(*args, **kwargs)
    Workers remote control.
    Availability: RabbitMQ (AMQP), Redis, and MongoDB transports.
```

**Examples**

```
$ celery control enable_events --timeout=5
$ celery control -d worker1@example.com enable_events
$ celery control -d w1.e.com, w2.e.com enable_events

$ celery control -d w1.e.com add_consumer queue_name
$ celery control -d w1.e.com cancel_consumer queue_name
$ celery control add_consumer queue exchange direct rkey
```

```python
call(method, arguments, **options)
control_group = 'control'
name = 'control'
class celery.bin.control.inspect(*args, **kwargs)
    Inspect the worker at runtime.
    Availability: RabbitMQ (AMQP) and Redis transports.
```

**Examples**

```
$ celery inspect active --timeout=5
$ celery inspect scheduled -d worker1@example.com
$ celery inspect revoked -d w1@e.com, w2@e.com
```

```python
call(method, arguments, **options)
control_group = 'inspect'
name = 'inspect'
class celery.bin.control.status(app=None, get_app=None, no_color=False, std-
    out=None, stderr=None, quiet=False, on_error=None, on_usage_error=None)
    Show list of workers that are online.
```

```python
option_list = None
run(*args, **kwargs)
```
3.11.73 celery.bin.list

The `celery list bindings` command, used to inspect queue bindings.

```python
class celery.bin.list.list_(app=None, get_app=None, no_color=False, stdout=None, stderr=None, quiet=False, on_error=None, on_usage_error=None):
    Get info from broker.
```

**Note:** For RabbitMQ the management plugin is required.

**Example**

```bash
$ celery list bindings
args = '[bindings]'
list_bindings(management)
run(what=None, *_, **kw)
```

3.11.74 celery.bin.migrate

The `celery migrate` command, used to filter and move messages.

```python
class celery.bin.migrate.migrate(app=None, get_app=None, no_color=False, stdout=None, stderr=None, quiet=False, on_error=None, on_usage_error=None):
    Migrate tasks from one broker to another.
```

**Warning:** This command is experimental, make sure you have a backup of the tasks before you continue.

**Example**

```bash
$ celery migrate amqp://A.example.com amqp://guest@B.example.com//
$ celery migrate redis://localhost amqp://guest@localhost//
```

```python
add_arguments(parser)
args = '<source_url> <dest_url>'
on_migrate_task(state, body, message)
progress_fmt = 'Migrating task {state.count}/{state.strtotal}: {body[task]}[{body[id]}]
run(source, destination, **kwargs)
```

3.11.75 celery.bin.purge

The `celery purge` program, used to delete messages from queues.
**class** `celery.bin.purge.purge`(*app=None*, *get_app=None*, *no_color=False*, *stdout=None*, *stderr=None*, *quiet=False*, *on_error=None*, *on_usage_error=None*)

Erase all messages from all known task queues.

**Warning:** There’s no undo operation for this command.

**add_arguments** *(parser)*

```
fmt_empty = 'No messages purged from {qnum} {queues}'
fmt_purged = 'Purged {mnum} {messages} from {qnum} known task {queues}.'
run (force=False, queues=None, exclude_queues=None, **kwargs)
```

```
warn_prelude = '{warning}: This will remove all tasks from {queues}: {names}.
There is no undo for this operation!

(to skip this prompt use the -f option)
```

```
warn_prompt = 'Are you sure you want to delete all tasks'
```

### 3.11.76 celery.bin.result

The `celery result` program, used to inspect task results.

**class** `celery.bin.result.result`(*app=None*, *get_app=None*, *no_color=False*, *stdout=None*, *stderr=None*, *quiet=False*, *on_error=None*, *on_usage_error=None*)

Gives the return value for a given task id.

**Examples**

```
$ celery result 8f511516-e2f5-4da4-9d2f-0fb83a86e500
$ celery result 8f511516-e2f5-4da4-9d2f-0fb83a86e500 -t tasks.add
$ celery result 8f511516-e2f5-4da4-9d2f-0fb83a86e500 --traceback
```

**add_arguments** *(parser)*

```
args = '<task_id>'
run (task_id, *args, **kwargs)
```

### 3.11.77 celery.bin.shell

The `celery shell` program, used to start a REPL.

**class** `celery.bin.shell.shell`(*app=None*, *get_app=None*, *no_color=False*, *stdout=None*, *stderr=None*, *quiet=False*, *on_error=None*, *on_usage_error=None*)

Start shell session with convenient access to celery symbols.

The following symbols will be added to the main globals:

- `celery`: the current application.
- `chord, group, chain, chunks, xmap, xstarmap, subtask, Task`
- all registered tasks.

**add_arguments** *(parser)*
invoke_bpython_shell()
invoke_default_shell()
invoke_fallback_shell()
invoke_ipython_shell()
run(*args, **kwargs)

3.11.78 celery.bin.upgrade

The celery upgrade command, used to upgrade from previous versions.

class celery.bin.upgrade.upgrade(app=None, get_app=None, no_color=False, std-
out=None, stderr=None, quiet=False, on_error=None, on_usage_error=None)

Perform upgrade between versions.

def add_arguments(parser):
choices = {'settings'}
run(*args, **kwargs)

def settings(command, filename=None, no_backup=False, django=False, compat=False, **kwargs)

def usage(command)

3.12 Internals

Release 4.4

3.12.1 Contributors Guide to the Code

- Philosophy
  - The API>RCP Precedence Rule
- Conventions and Idioms Used
  - Classes
    * Naming
    * Default values
    * Exceptions
    * Composites
- Applications vs. “single mode”
- Module Overview
- Worker overview
Philosophy

The API-RCP Precedence Rule

- The API is more important than Readability
- Readability is more important than Convention
- **Convention is more important than Performance**
  - ...unless the code is a proven hot-spot.

More important than anything else is the end-user API. Conventions must step aside, and any suffering is always alleviated if the end result is a better API.

Conventions and Idioms Used

Classes

Naming

- Follows PEP 8.
- Class names must be *CamelCase*.
- but not if they’re verbs, verbs shall be *lower_case*:

```python
# - test case for a class
class TestMyClass(Case):  # BAD
    pass

class test_MyClass(Case):  # GOOD
    pass

# - test case for a function
class TestMyFunction(Case):  # BAD
    pass

class test_my_function(Case):  # GOOD
    pass

# - “action” class (verb)
class UpdateTwitterStatus(object):  # BAD
    pass

class update_twitter_status(object):  # GOOD
    pass
```

**Note:** Sometimes it makes sense to have a class mask as a function, and there’s precedence for this in the Python standard library (e.g., `contextmanager`). Celery examples include `signature`, `chord`, `inspect`, `promise` and more.

- Factory functions and methods must be *CamelCase* (excluding verbs):
class Celery(object):
    
def consumer_factory(self):  # BAD
        ...
    
def Consumer(self):  # GOOD
        ...

Default values

Class attributes serve as default values for the instance, as this means that they can be set by either instantiation or inheritance.

Example:

```python
class Producer(object):
    active = True
    serializer = 'json'

    def __init__(self, serializer=None, active=None):
        self.serializer = serializer or self.serializer

        # must check for None when value can be false-y
        self.active = active if active is not None else self.active
```

A subclass can change the default value:

```python
class TaskProducer(Producer):
    serializer = 'pickle'
```

and the value can be set at instantiation:

```python
>>> producer = TaskProducer(serializer='msgpack')
```

Exceptions

Custom exceptions raised by an objects methods and properties should be available as an attribute and documented in the method/property that throw.

This way a user doesn’t have to find out where to import the exception from, but rather use `help(obj)` and access the exception class from the instance directly.

Example:

```python
class Empty(Exception):
    pass

class Queue(object):
    Empty = Empty

    def get(self):
        ### Get the next item from the queue.
        :raises Queue.Empty: if there are no more items left.
```

(continues on next page)
Composites

Similarly to exceptions, composite classes should be override-able by inheritance and/or instantiation. Common sense can be used when selecting what classes to include, but often it’s better to add one too many: predicting what users need to override is hard (this has saved us from many a monkey patch).

Example:

```python
class Worker(object):
    Consumer = Consumer

    def __init__(self, connection, consumer_cls=None):
        self.Consumer = consumer_cls or self.Consumer

    def do_work(self):
        with self.Consumer(self.connection) as consumer:
            self.connection.drain_events()
```

Applications vs. “single mode”

In the beginning Celery was developed for Django, simply because this enabled us get the project started quickly, while also having a large potential user base.

In Django there’s a global settings object, so multiple Django projects can’t co-exist in the same process space, this later posed a problem for using Celery with frameworks that don’t have this limitation.

Therefore the app concept was introduced. When using apps you use ‘celery’ objects instead of importing things from Celery sub-modules, this (unfortunately) also means that Celery essentially has two API’s.

Here’s an example using Celery in single-mode:

```python
from celery import task
from celery.task.control import inspect

from .models import CeleryStats

@task
def write_stats_to_db():
    stats = inspect().stats(timeout=1)
    for node_name, reply in stats:
        CeleryStats.objects.update_stat(node_name, stats)
```

and here’s the same using Celery app objects:

```python
from .celery import celery
from .models import CeleryStats
```
```python
@app.task
def write_stats_to_db():
    stats = celery.control.inspect().stats(timeout=1)
    for node_name, reply in stats:
        CeleryStats.objects.update_stat(node_name, stats)
```

In the example above the actual application instance is imported from a module in the project, this module could look something like this:

```python
from celery import Celery
app = Celery(broker='amqp://')
```

**Module Overview**

- **celery.app**
  
  This is the core of Celery: the entry-point for all functionality.

- **celery.loaders**
  
  Every app must have a loader. The loader decides how configuration is read; what happens when the worker starts; when a task starts and ends; and so on.

  The loaders included are:
  
  - **app**
    
    Custom Celery app instances uses this loader by default.
  
  - **default**
    
    “single-mode” uses this loader by default.

  Extension loaders also exist, for example **celery-pylons**.

- **celery.worker**
  
  This is the worker implementation.

- **celery.backends**
  
  Task result backends live here.

- **celery.apps**
  
  Major user applications: worker and beat. The command-line wrappers for these are in celery.bin (see below)

- **celery.bin**
  
  Command-line applications. `setup.py` creates setuptools entry-points for these.

- **celery.concurrency**
  
  Execution pool implementations (prefork, eventlet, gevent, solo, thread).

- **celery.db**
  
  Database models for the SQLAlchemy database result backend. (should be moved into `celery.backends.database`)

- **celery.events**
Sending and consuming monitoring events, also includes curses monitor, event dumper and utilities to work with in-memory cluster state.

- **celery.execute.trace**
  
  How tasks are executed and traced by the worker, and in eager mode.

- **celery.security**
  
  Security related functionality, currently a serializer using cryptographic digests.

- **celery.task**
  
  single-mode interface to creating tasks, and controlling workers.

- **t.unit (int distribution)**
  
  The unit test suite.

- **celery.utils**
  
  Utility functions used by the Celery code base. Much of it is there to be compatible across Python versions.

- **celery.contrib**
  
  Additional public code that doesn’t fit into any other name-space.

### Worker overview

- **celery.bin.worker:Worker**

  This is the command-line interface to the worker.

  **Responsibilities:**
  - Daemonization when `--detach` set,
  - dropping privileges when using `--uid`/`--gid` arguments
  - Installs “concurrency patches” (eventlet/gevent monkey patches).

  ```python
  app.worker_main(argv) calls instantiate('celery.bin.worker:Worker')(app).
  execute_from_commandline(argv)
  ```

- **app.Worker -> celery.apps.worker:Worker**

  Responsibilities:  
  * sets up logging and redirects standard outs  
  * installs signal handlers (`TERM/HUP/STOP/USR1 (cry)/USR2 (rdb)`)  
  * prints banner and warnings (e.g., pickle warning)  
  * handles the `celery worker --purge` argument

- **app.WorkController -> celery.worker.WorkController**

  This is the real worker, built up around bootsteps.

### 3.12.2 Celery Deprecation Time-line

- **Removals for version 5.0**
  
  - **Old Task API**
    
    * **Compat Task Modules**
Removals for version 5.0

Old Task API

Compat Task Modules

- Module `celery.decorators` will be removed:
  This means you need to change:
  ```python
  from celery.decorators import task
  ```
  Into:
  ```python
  from celery import task
  ```

- Module `celer.y.task` may be removed (not decided)
  This means you should change:
  ```python
  from celery.task import task
  ```
  into:
  ```python
  from celery import task
  ```
  —and:
  ```python
  from celery.task import Task
  ```
  into:
  ```python
  from celery import Task
  ```

Note that the new `Task` class no longer uses `classmethod()` for these methods:

- delay
- apply_async
- retry
• apply
• AsyncResult
• subtask

This also means that you can’t call these methods directly on the class, but have to instantiate the task first:

```python
>>> MyTask.delay() # NO LONGER WORKS
>>> MyTask().delay() # WORKS!
```

**Task attributes**

The task attributes:

- queue
- exchange
- exchange_type
- routing_key
- delivery_mode
- priority

is deprecated and must be set by `task_routes` instead.

**Modules to Remove**

- `celery.execute`
  This module only contains `send_task`: this must be replaced with `app.send_task` instead.
- `celery.decorators`
  See *Compat Task Modules*
- `celery.log`
  Use `app.log` instead.
- `celery.messaging`
  Use `app.amqp` instead.
- `celery.registry`
  Use `celery.app.registry` instead.
- `celery.task.control`
  Use `app.control` instead.
- `celery.task.schedules`
  Use `celery.schedules` instead.
- `celery.task.chords`
  Use `celery.chord()` instead.
Settings

**BROKER Settings**

<table>
<thead>
<tr>
<th>Setting name</th>
<th>Replace with</th>
</tr>
</thead>
<tbody>
<tr>
<td>BROKER_HOST</td>
<td>broker_url</td>
</tr>
<tr>
<td>BROKER_PORT</td>
<td>broker_url</td>
</tr>
<tr>
<td>BROKER_USER</td>
<td>broker_url</td>
</tr>
<tr>
<td>BROKER_PASSWORD</td>
<td>broker_url</td>
</tr>
<tr>
<td>BROKER_VHOST</td>
<td>broker_url</td>
</tr>
</tbody>
</table>

**REDIS Result Backend Settings**

<table>
<thead>
<tr>
<th>Setting name</th>
<th>Replace with</th>
</tr>
</thead>
<tbody>
<tr>
<td>CELERY.Redis_HOST</td>
<td>result_backend</td>
</tr>
<tr>
<td>CELERY.Redis_PORT</td>
<td>result_backend</td>
</tr>
<tr>
<td>CELERY.Redis_DB</td>
<td>result_backend</td>
</tr>
<tr>
<td>CELERY.Redis_PASSWORD</td>
<td>result_backend</td>
</tr>
<tr>
<td>REDIS_HOST</td>
<td>result_backend</td>

<tr>
<td>REDIS_PORT</td>
<td>result_backend</td>
</tr>
<tr>
<td>REDIS_DB</td>
<td>result_backend</td>
</tr>
<tr>
<td>REDIS_PASSWORD</td>
<td>result_backend</td>
</tr>
</tbody>
</table>

**Task_sent signal**

The `task_sent` signal will be removed in version 4.0. Please use the `before_task_publish` and `after_task_publish` signals instead.

**Result**

Apply to: `AsyncResult`, `EagerResult`:

- `Result.wait()` → `Result.get()`
- `Result.task_id()` → `Result.id`
- `Result.status` → `Result.state`

**Settings**

<table>
<thead>
<tr>
<th>Setting name</th>
<th>Replace with</th>
</tr>
</thead>
<tbody>
<tr>
<td>CELERY_AMQP_TASK_RESULT_EXPIRES</td>
<td>result_expired</td>
</tr>
</tbody>
</table>

**Removals for version 2.0**

- The following settings will be removed:
<table>
<thead>
<tr>
<th>Setting name</th>
<th>Replace with</th>
</tr>
</thead>
<tbody>
<tr>
<td>CELERY_AMQP_CONSUMER_QUEUES</td>
<td>task_queues</td>
</tr>
<tr>
<td>CELERY_AMQP_CONSUMER_QUEUES</td>
<td>task_queues</td>
</tr>
<tr>
<td>CELERY_AMQP_EXCHANGE</td>
<td>task_default_exchange</td>
</tr>
<tr>
<td>CELERY_AMQP_EXCHANGE_TYPE</td>
<td>task_default_exchange_type</td>
</tr>
<tr>
<td>CELERY_AMQP_CONSUMER_ROUTING_KEY</td>
<td>task_queues</td>
</tr>
<tr>
<td>CELERY_AMQP_PUBLISHER_ROUTING_KEY</td>
<td>task_default_routing_key</td>
</tr>
</tbody>
</table>

- **CELERY_LOADER** definitions without class name.

  For example, `celery.loaders.default`, needs to include the class name: `celery.loaders.default.Loader`.

- **TaskSet.run()**. Use `celery.task.base.TaskSet.apply_async()` instead.

### 3.12.3 Internals: The worker

**Introduction**

The worker consists of 4 main components: the consumer, the scheduler, the mediator and the task pool. All these components runs in parallel working with two data structures: the ready queue and the ETA schedule.

**Data structures**

**timer**

The timer uses `heapq` to schedule internal functions. It’s very efficient and can handle hundred of thousands of entries.

**Components**

**Consumer**

Receives messages from the broker using `Kombu`.

When a message is received it’s converted into a `celery.worker.request.Request` object.
Tasks with an ETA, or rate-limit are entered into the timer, messages that can be immediately processed are sent to the execution pool.

ETA and rate-limit when used together will result in the rate limit being observed with the task being scheduled after the ETA.

**Timer**

The timer schedules internal functions, like cleanup and internal monitoring, but also it schedules ETA tasks and rate limited tasks. If the scheduled tasks ETA has passed it is moved to the execution pool.

**TaskPool**

This is a slightly modified `multiprocessing.Pool`. It mostly works the same way, except it makes sure all of the workers are running at all times. If a worker is missing, it replaces it with a new one.

### 3.12.4 Message Protocol

- **Task messages**
  - **Version 2**
    - **Definition**
    - **Example**
    - **Changes from version 1**
  - **Version 1**
    - **Message body**
    - **Example message**

### Task messages

#### Version 2

#### Definition

```python
properties = {
    'correlation_id': uuid task_id,
    'content_type': string mimetype,
    ...
}
```

(continues on next page)
```python
'content_encoding': string encoding,

# optional
'reply_to': string queue_or_url,
}
headers = {
    'lang': string 'py'
    'task': string task,
    'id': uuid task_id,
    'root_id': uuid root_id,
    'parent_id': uuid parent_id,
    'group': uuid group_id,

    # optional
    'meth': string method_name,
    'shadow': string alias_name,
    'eta': iso8601 ETA,
    'expires': iso8601 expires,
    'retries': int retries,
    'timelimit': (soft, hard),
    'argsrepr': str repr(args),
    'kwargsrepr': str repr(kwvars),
    'origin': str nodename,
}
body = {
    object[] args,
    Mapping kwars,
    Mapping embed {
        'callbacks': Signature[] callbacks,
        'errbacks': Signature[] errbacks,
        'chain': Signature[] chain,
        'chord': Signature chord_callback,
    }
}
```

**Example**

This example sends a task message using version 2 of the protocol:

```python
import json
import os
import socket

import asyncio

# chain: add(add(add(2, 2), 4), 8) == 2 + 2 + 4 + 8

args = (2, 2)
kwars = {}

await basic_publish(
    message=json.dumps((args, kwars, None),
    application_headers={
        'lang': 'py',
        'task': 'proj.tasks.add',
        'argsrepr': repr(args),
```
Changes from version 1

- Protocol version detected by the presence of a task message header.
- Support for multiple languages via the lang header.
  Worker may redirect the message to a worker that supports the language.
- Meta-data moved to headers.
  This means that workers/intermediates can inspect the message and make decisions based on the headers without decoding the payload (that may be language specific, for example serialized by the Python specific pickle serializer).
- Always UTC
  There’s no utc flag anymore, so any time information missing timezone will be expected to be in UTC time.
- Body is only for language specific data.
  - Python stores args/kwargqs and embedded signatures in body.
  - If a message uses raw encoding then the raw data will be passed as a single argument to the function.
  - Java/C, etc. can use a Thrift/protobuf document as the body
- origin is the name of the node sending the task.
- Dispatches to actor based on task, meth headers
  meth is unused by Python, but may be used in the future to specify class+method pairs.
- Chain gains a dedicated field.
  Reducing the chain into a recursive callbacks argument causes problems when the recursion limit is exceeded.
  This is fixed in the new message protocol by specifying a list of signatures, each task will then pop a task off the list when sending the next message:

```python
execute_task(message)
chain = embed['chain']
if chain:
    sig = maybe_signature(chain.pop())
    sig.apply_async(chain=chain)
```

- correlation_id replaces task_id field.
- root_id and parent_id fields helps keep track of work-flows.
• shadow lets you specify a different name for logs, monitors can be used for concepts like tasks that calls a function specified as argument:

```python
from celery.utils.imports import qualname

class PickleTask(Task):
    def unpack_args(self, fun, args=()):
        return fun, args
    def apply_async(self, args, kwargs, **options):
        fun, real_args = self.unpack_args(*args)
        return super(PickleTask, self).apply_async((fun, real_args, kwargs), shadow=qualname(fun), **options)

@app.task(base=PickleTask)
def call(fun, args, kwargs):
    return fun(*args, **kwargs)
```

Version 1

In version 1 of the protocol all fields are stored in the message body: meaning workers and intermediate consumers must deserialize the payload to read the fields.

Message body

• task
  string
  Name of the task. required

• id
  string
  Unique id of the task (UUID). required

• args
  list
  List of arguments. Will be an empty list if not provided.

• kwargs
  dictionary
  Dictionary of keyword arguments. Will be an empty dictionary if not provided.

• retries
  int
  Current number of times this task has been retried. Defaults to 0 if not specified.

• eta
  string (ISO 8601)
Estimated time of arrival. This is the date and time in ISO 8601 format. If not provided the message isn’t scheduled, but will be executed asap.

- **expires**
  - *string (ISO 8601)*
  New in version 2.0.2.
  Expiration date. This is the date and time in ISO 8601 format. If not provided the message will never expire. The message will be expired when the message is received and the expiration date has been exceeded.

- **taskset**
  - *string*
  The group this task is part of (if any).

- **chord**
  - *Signature*
  New in version 2.3.
  Signifies that this task is one of the header parts of a chord. The value of this key is the body of the cord that should be executed when all of the tasks in the header has returned.

- **utc**
  - *bool*
  New in version 2.5.
  If true time uses the UTC timezone, if not the current local timezone should be used.

- **callbacks**
  - <list>Signature
  New in version 3.0.
  A list of signatures to call if the task exited successfully.

- **errbacks**
  - <list>Signature
  New in version 3.0.
  A list of signatures to call if an error occurs while executing the task.

- **timelimit**
  - <tuple>(float, float)
  New in version 3.1.
  Task execution time limit settings. This is a tuple of hard and soft time limit value (int/float or None for no limit).
  Example value specifying a soft time limit of 3 seconds, and a hard time limit of 10 seconds:

```python
{'timelimit': (3.0, 10.0)}
```
Example message

This is an example invocation of a celery.task.ping task in json format:

```json
{"id": "4cc7438e-af04-4f8f-a2f3-f46567e7ca77",
 "task": "celery.task.PingTask",
 "args": [],
 "kwargs": {},
 "retries": 0,
 "eta": "2009-11-17T12:30:56.527191"}
```

Task Serialization

Several types of serialization formats are supported using the content_type message header. The MIME-types supported by default are shown in the following table.

<table>
<thead>
<tr>
<th>Scheme</th>
<th>MIME Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>json</td>
<td>application/json</td>
</tr>
<tr>
<td>yaml</td>
<td>application/x-yaml</td>
</tr>
<tr>
<td>pickle</td>
<td>application/x-python-serialize</td>
</tr>
<tr>
<td>msgpack</td>
<td>application/x-msgpack</td>
</tr>
</tbody>
</table>

Event Messages

Event messages are always JSON serialized and can contain arbitrary message body fields. Since version 4.0, the body can consist of either a single mapping (one event), or a list of mappings (multiple events). There are also standard fields that must always be present in an event message:

**Standard body fields**

- **string type**
  
  The type of event. This is a string containing the category and action separated by a dash delimiter (e.g., task-succeeded).

- **string hostname**
  
  The fully qualified hostname of where the event occurred at.

- **unsigned long long clock**
  
  The logical clock value for this event (Lamport time-stamp).

- **float timestamp**
  
  The UNIX time-stamp corresponding to the time of when the event occurred.

- **signed short utcoffset**
  
  This field describes the timezone of the originating host, and is specified as the number of hours ahead of/behind UTC (e.g., -2 or +1).

- **unsigned long long pid**
The process id of the process the event originated in.

**Standard event types**

For a list of standard event types and their fields see the *Event Reference*.

**Example message**

This is the message fields for a *task-succeeded* event:

```python
properties = {
    'routing_key': 'task.succeeded',
    'exchange': 'celeryev',
    'content_type': 'application/json',
    'content_encoding': 'utf-8',
    'delivery_mode': 1,
}
headers = {
    'hostname': 'worker1@george.vandelay.com',
}
body = {
    'type': 'task-succeeded',
    'hostname': 'worker1@george.vandelay.com',
    'pid': 6335,
    'clock': 393912923921,
    'timestamp': 1401717709.101747,
    'utcoffset': -1,
    'uuid': '9011d855-fdd1-4f8f-adb3-a413b499eafb',
    'retval': 4,
    'runtime': 0.0003212,
}
```

**3.12.5 “The Big Instance” Refactor**

The *app* branch is a work-in-progress to remove the use of a global configuration in Celery.

Celery can now be instantiated and several instances of Celery may exist in the same process space. Also, large parts can be customized without resorting to monkey patching.

**Examples**

Creating a Celery instance:

```python
>>> from celery import Celery
>>> app = Celery()
>>> app.config_from_object('celeryconfig')
>>> #app.config_from_envvar('CELERY_CONFIG_MODULE')
```

Creating tasks:

```python
@app.task
def add(x, y):
    return x + y
```
Creating custom Task subclasses:

```python
Task = celery.create_task_cls()

class DebugTask(Task):
    
def on_failure(self, *args, **kwargs):
        import pdb
        pdb.set_trace()

@app.task(base=DebugTask)
def add(x, y):
    return x + y
```

Starting a worker:

```python
worker = celery.Worker(loglevel='INFO')
```

Getting access to the configuration:

```python
celery.conf.task_always_eager = True
celery.conf['task_always_eager'] = True
```

Controlling workers:

```python
>>> celery.control.inspect().active()
>>> celery.control.rate_limit(add.name, '100/m')
>>> celery.control.broadcast('shutdown')
>>> celery.control.discard_all()
```

Other interesting attributes:

```python
# Establish broker connection.
>>> celery.broker_connection()

# AMQP Specific features.
>>> celery.amqp
>>> celery.amqp.Router
>>> celery.amqp.get_queues()
>>> celery.amqp.get_task_consumer()

# Loader
>>> celery.loader

# Default backend
>>> celery.backend
```

As you can probably see, this really opens up another dimension of customization abilities.

**Deprecated**

- `celery.task.ping celery.task.PingTask`

  Inferior to the ping remote control command. Will be removed in Celery 2.3.
Aliases (Pending deprecation)

- **celery.task.base**
  - .Task -> {app.Task/ celery.app.task.Task}

- **celery.task.sets**
  - .TaskSet -> {app.TaskSet}

- **celery.decorators/celery.task**
  - .task -> {app.task}

- **celery.execute**
  - .apply_async -> {task.apply_async}
  - .apply -> {task.apply}
  - .send_task -> {app.send_task}
  - .delay_task -> *no alternative*

- **celery.log**
  - .get_default_logger -> {app.log.get_default_logger}
  - .setup_logger -> {app.log.setup_logger}
  - .get_task_logger -> {app.log.get_task_logger}
  - .setup_task_logger -> {app.log.setup_task_logger}
  - .setup_logging_subsystem -> {app.log.setup_logging_subsystem}
  - .redirect_stdouts_to_logger -> {app.log.redirect_stdouts_to_logger}

- **celery.messaging**
  - .establish_connection -> {app.broker_connection}
  - .with_connection -> {app.with_connection}
  - .get_consumer_set -> {app.amqp.get_task_consumer}
  - .TaskPublisher -> {app.amqp.TaskPublisher}
  - .TaskConsumer -> {app.amqp.TaskConsumer}
  - .ConsumerSet -> {app.amqp.ConsumerSet}

- **celery.conf.*** -> {app.conf}

**NOTE:** All configuration keys are now named the same as in the configuration. So the key `task_always_eager` is accessed as:

```python
>>> app.conf.task_always_eager
```

instead of:

```python
>>> from celery import conf
>>> conf.always_eager

  - .get_queues -> {app.amqp.get_queues}
```

- **celery.task.control**
- .broadcast -> {app.control.broadcast}
- .rate_limit -> {app.control.rate_limit}
- .ping -> {app.control.ping}
- .revoke -> {app.control.revoke}
- .discard_all -> {app.control.discard_all}
- .inspect -> {app.control.inspect}

• celery.utils.info
  - .humanize_seconds -> celery.utils.time.humanize_seconds
  - .textindent -> celery.utils.textindent
  - .get_broker_info -> {app.amqp.get_broker_info}
  - .format_broker_info -> {app.amqp.format_broker_info}
  - .format_queues -> {app.amqp.format_queues}

Default App Usage

To be backward compatible, it must be possible to use all the classes/functions without passing an explicit app instance. This is achieved by having all app-dependent objects use default_app if the app instance is missing.

```python
from celery.app import app_or_default

class SomeClass(object):
    def __init__(self, app=None):
        self.app = app_or_default(app)
```

The problem with this approach is that there’s a chance that the app instance is lost along the way, and everything seems to be working normally. Testing app instance leaks is hard. The environment variable CELERY_TRACE_APP can be used, when this is enabled celery.app.app_or_default() will raise an exception whenever it has to go back to the default app instance.

App Dependency Tree

• {app}
  - celery.loaders.base.BaseLoader
  - celery.backends.base.BaseBackend
  - {app.TaskSet}
    * celery.task.sets.TaskSet (app.TaskSet)
  - {app.TaskSetResult}
    * celery.result.TaskSetResult (app.TaskSetResult)
• {app.AsyncResult}

3.12.6 Internal Module Reference

Release 4.4

Date Dec 16, 2019

celery.worker.components

Worker-level Bootsteps.

class celery.worker.components.Timer(parent, **kwargs)
  Timer bootstep.
  create(w)
    Create the step.
  name = 'celery.worker.components.Timer'
on_timer_error(ex)

on_timer_tick(delay)

class celery.worker.components.Hub(w, **kwargs)
Worker starts the event loop.

create(w)
Create the step.

include_if(w)
Return true if step should be included.

You can define this as an optional predicate that decides whether this step should be created.

name = 'celery.worker.components.Hub'
requires = (step:celery.worker.components.Timer{()},)
start(w)
stop(w)
terminate(w)

class celery.worker.components.Pool(w, autoscale=None, **kwargs)
Bootstep managing the worker pool.

Describes how to initialize the worker pool, and starts and stops the pool during worker start-up/shutdown.

Adds attributes:
• autoscale
• pool
• max_concurrency
• min_concurrency

close(w)
create(w)
Create the step.

info(w)

name = 'celery.worker.components.Pool'
register_with_event_loop(w, hub)
requires = (step:celery.worker.components.Hub{(step:celery.worker.components.Timer{()})},)
terminate(w)

class celery.worker.components.Beat(w, beat=False, **kwargs)
Step used to embed a beat process.

Enabled when the beat argument is set.

conditional = True
create(w)
Create the step.

label = 'Beat'

name = 'celery.worker.components.Beat'

class celery.worker.components.StateDB(w, **kwargs)
Bootstep that sets up between-restart state database file.
create(w)
  Create the step.

name = 'celery.worker.components.StateDB'

class celery.worker.components.Consumer(parent, **kwargs)
  Bootstrap starting the Consumer blueprint.

create(w)
  Create the step.

last = True
name = 'celery.worker.components.Consumer'

celery.worker.loops

The consumers highly-optimized inner loop.

celery.worker.loops.asynloop(obj, connection, consumer, blueprint, hub, qos, heartbeat, clock, hbrate=2.0)
  Non-blocking event loop.

celery.worker.loops.synloop(obj, connection, consumer, blueprint, hub, qos, heartbeat, clock, hbrate=2.0, **kwargs)
  Fallback blocking event loop for transports that doesn’t support AIO.

celery.worker.heartbeat

Heartbeat service.

This is the internal thread responsible for sending heartbeat events at regular intervals (may not be an actual thread).

class celery.worker.heartbeat.Heart(timer, eventer, interval=None)
  Timer sending heartbeats at regular intervals.

Parameters
  • timer (kombu.asynchronous.timer.Timer) – Timer to use.
  • eventer (celery.events.EventDispatcher) – Event dispatcher to use.
  • interval (float) – Time in seconds between sending heartbeats. Default is 2 seconds.

start()
stop()

celery.worker.control

Worker remote control command implementations.

class celery.worker.control.Panel(**kwargs)
  Global registry of remote control commands.

data = {'active': <function active>, 'active_queues': <function active_queues>, 'add':
meta = {'active': controller_info_t(alias='dump_active', type='inspect', visible=True,
classmethod register(*args, **kwargs)
  Register a virtual subclass of an ABC.

  Returns the subclass, to allow usage as a class decorator.
**celery.worker.pidbox**

Worker Pidbox (remote control).

```python
class celery.worker.pidbox.Pidbox(c):
    Worker mailbox.
    consumer = None
    on_message(body, message)
    on_stop()
    reset()
    shutdown(c)
    start(c)
    stop(c)
```

```python
class celery.worker.pidbox.gPidbox(c):
    Worker pidbox (greenlet).
    loop(c)
    on_stop()
    reset()
    start(c)
```

**celery.worker.autoscale**

Pool Autoscaling.

This module implements the internal thread responsible for growing and shrinking the pool according to the current autoscale settings.

The autoscale thread is only enabled if the `celery worker --autoscale` option is used.

```python
class celery.worker.autoscale.Autoscaler(pool, max_concurrency, min_concurrency=0, worker=None, keepalive=30.0, mutex=None):
    Background thread to autoscale pool workers.
    body()
    force_scale_down(n)
    force_scale_up(n)
    info()
    maybe_scale(req=None)
    processes
    qty
    scale_down(n)
    scale_up(n)
    update(max=None, min=None)
```

```python
class celery.worker.autoscale.WorkerComponent(w, **kwargs):
    Bootstep that starts the autoscaler thread/timer in the worker.
```
conditional = True

create(w)
    Create the step.

info(w)
    Return Autoscaler info.

label = 'Autoscaler'
name = 'celery.worker.autoscale.WorkerComponent'

register_with_event_loop(w, hub)

```

celery.concurrency

Pool implementation abstract factory, and alias definitions.

celery.concurrency.get_implementation(cls)
    Return pool implementation by name.

celery.concurrency.solo

Single-threaded execution pool.

class celery.concurrency.solo.TaskPool(*args, **kwargs)
    Solo task pool (blocking, inline, fast).

    body_can_be_buffer = True

celery.concurrency.prefork

Prefork execution pool.

Pool implementation using multiprocessing.

class celery.concurrency.prefork.TaskPool(limit=None, putlocks=True, forking_enable=True, callbacks_propagate=(), app=None, **options)

    Multiprocessing Pool implementation.

    BlockingPool
        alias of billiard.pool.Pool

    Pool
        alias of celery.concurrency.asynpool.AsynPool

did_start_ok()

num_processes

on_close()

on_start()

on_stop()
    Gracefully stop the pool.

on_terminate()
    Force terminate the pool.
```
```
register_with_event_loop(loop)
restart()
uses_semaphore = True
write_stats = None

celery.concurrency.prefork.process_initializer(app, hostname)
Pool child process initializer.
Initialize the child pool process to ensure the correct app instance is used and things like logging works.

celery.concurrency.prefork.process_destructor(pid, exitcode)
Pool child process destructor.
Dispatch the worker_process_shutdown signal.

celery.concurrency.eventlet
Eventlet execution pool.

class celery.concurrency.eventlet.TaskPool(*args, **kwargs)
Eventlet Task Pool.

class Timer(*args, **kwargs)
Eventlet Timer.

cancel(tref)
clear()
queue
   Snapshot of underlying datastructure.
grow(n=1)
is_green = True
on_apply(target, args=None, kwargs=None, callback=None, accept_callback=None, **_)
on_start()
on_stop()
shrink(n=1)
signal_safe = False
task_join_will_block = False

celery.concurrency.gevent
Gevent execution pool.

class celery.concurrency.gevent.TaskPool(*args, **kwargs)
GEvent Pool.

class Timer(*args, **kwargs)

clear()
queue
   Snapshot of underlying datastructure.
```
grow(n=1)

is_green = True

num_processes

on_apply(target, args=None, kwargs=None, callback=None, accept_callback=None, timeout=None, timeout_callback=None, apply_target=<function apply_target>, **_)

on_start()

on_stop()

shrink(n=1)

signal_safe = False

task_join_will_block = False

celery.concurrency.thread

Thread execution pool.

class celery.concurrency.thread.TaskPool(*args, **kwargs)

Thread Task Pool.

body_can_be_buffer = True

on_apply(target, args=None, kwargs=None, callback=None, accept_callback=None, **_)

on_stop()

signal_safe = False

celery.concurrency.base

Base Execution Pool.

class celery.concurrency.base.BasePool(limit=None, putlocks=True, forking_enable=True, callbacks_propagate=(), app=None, **options)

Task pool.

CLOSE = 2

RUN = 1

TERMINATE = 3

class Timer(schedule=None, on_error=None, on_tick=None, on_start=None, max_interval=None, **kwargs)

Timer thread.

Note: This is only used for transports not supporting AsyncIO.

class Entry(fun, args=None, kwargs=None)

Schedule Entry.

args

cancel()
cancelled

fun

dict

kwargs

tref

Schedule

alias of kombu.asynchronous.timer.Timer

call_after(*args, **kwargs)
call_at (*args, **kwargs)
call_repeatedly (*args, **kwargs)
cancel(tref)
clear()
empty()
ensure_started()
enter(entry, eta, priority=None)
enter_after(*args, **kwargs)
extit_after(secs, priority=10)
next()
on_tick = None
queue

run()

Method representing the thread’s activity.

You may override this method in a subclass. The standard run() method invokes the callable object passed to the object’s constructor as the target argument, if any, with sequential and keyword arguments taken from the args and kwargs arguments, respectively.

running = False

stop()

active

apply_async(target, args=None, kwargs=None, **options)

Equivalent of the apply() built-in function.

Callbacks should optimally return as soon as possible since otherwise the thread which handles the result will get blocked.

body_can_be_buffer = False

close()

did_start_ok()

flush()

info

is_green = False

set to true if pool uses greenlets.
maintain_pool(*args, **kwargs)
num_processes
on_apply(*args, **kwargs)
on_close()
on_hard_timeout(job)
on_soft_timeout(job)
on_start()
on_stop()
on_terminate()
register_with_event_loop(loop)
restart()
signal_safe = True
  set to true if the pool can be shutdown from within a signal handler.
start()
stop()
task_join_will_block = True
terminate()
terminate_job(pid, signal=None)
uses_semaphore = False
  only used by multiprocessing pool

celery.concurrency.base.apply_target(target, args=(), kwargs=None, callback=None, accept_callback=None, pid=None, getpid=<built-in function getpid>, propagate=(), monotonic=<built-in function monotonic>, **_)

Apply function within pool context.

celery.backends

Result Backends.
celery.backends.get_backend_by_url(backend=None, loader=None)
  Deprecated alias to celery.app.backends.by_url().
celery.backends.get_backend_cls(backend=None, loader=None, **kwargs)
  Deprecated alias to celery.app.backends.by_name().

celery.backends.base

Result backend base classes.
  • BaseBackend defines the interface.
  • KeyValueStoreBackend is a common base class using K/V semantics like _get and _put.
**class celery.backends.base.BaseBackend**(app, serializer=None, max_cached_results=None, accept=None, expires=None, expires_type=None, url=None, **kwargs)

Base (synchronous) result backend.

**class celery.backends.base.KeyValueStoreBackend**(*args, **kwargs)

Result backend base class for key/value stores.

**class celery.backends.base.DisabledBackend**(app, serializer=None, max_cached_results=None, accept=None, expires=None, expires_type=None, url=None, **kwargs)

Dummy result backend.

**as_uri**(*args, **kwargs)

Return the backend as an URI, sanitizing the password or not.

**ensure_chords_allowed**()

**get_many**(*args, **kwargs)

**get_result**(*args, **kwargs)

**get_state**(*args, **kwargs)

**get_status**(*args, **kwargs)

**get_task_meta_for**(*args, **kwargs)

**get_traceback**(*args, **kwargs)

**store_result**(*args, **kwargs)

Update task state and result.

**wait_for**(*args, **kwargs)

---

**celery.backends.asynchronous**

Async I/O backend support utilities.

**class celery.backends.asynchronous.AsyncBackendMixin**

Mixin for backends that enables the async API.

**add_pending_result**(result, weak=False, start_drainer=True)

**add_pending_results**(results, weak=False)

**is_async**

**iter_native**(result, no_ack=True, **kwargs)

**on_result_fulfilled**(result)

**remove_pending_result**(result)

**wait_for_pending**(result, callback=None, propagate=True, **kwargs)

**class celery.backends.asynchronous.BaseResultConsumer**(backend, app, accept, pending_results, pending_messages)

Manager responsible for consuming result messages.

**cancel_for**(task_id)

**consume_from**(task_id)
```python
drain_events (timeout=None)
drain_events_until (p, timeout=None, on_interval=None)
on_after_fork ()
on_out_of_band_result (message)
on_state_change (meta, message)
on_wait_for_pending (result, timeout=None, **kwargs)
start (initial_task_id, **kwargs)
stop ()
class celery.backends.asynchronous.Drainer (result_consumer)
    Result draining service.
drain_events_until (p, timeout=None, on_interval=None, wait=None)
start ()
stop ()
wait_for (p, wait, timeout=None)
celery.backends.asynchronous.register_drainer (name)
    Decorator used to register a new result drainer type.

celery.backends.azureblockblob

The Azure Storage Block Blob backend for Celery.
class celery.backends.azureblockblob.AzureBlockBlobBackend (url=None, container_name=None,
    retry_initial_backoff_sec=None, retry_increment_base=None, retry_max_attempts=None,
    *args, **kwargs)
    Azure Storage Block Blob backend for Celery.

delete (key)
    Delete the value at a given key.
    Parameters key – The key of the value to delete.

get (key)
    Read the value stored at the given key.
    Parameters key – The key for which to read the value.

mget (keys)
    Read all the values for the provided keys.
    Parameters keys – The list of keys to read.

set (key, value)
    Store a value for a given key.
    Parameters
    • key – The key at which to store the value.
    • value – The value to store.
```
celery.backends.rpc

The **RPC** result backend for AMQP brokers.

**exception** celery.backends.rpc.BacklogLimitExceeded

Too much state history to fast-forward.

class celery.backends.rpc.RPCBackend(app, connection=None, exchange=None, exchange_type=None, persistent=None, serializer=None, auto_delete=True, **kwargs)

Base class for the RPC result backend.

**exception** BacklogLimitExceeded

Exception raised when there are too many messages for a task id.

class Consumer(channel, queues=None, no_ack=None, auto_declare=None, callbacks=None, on_decode_error=None, on_message=None, accept=None, prefetch_count=None, tag_prefix=None)

Consumer that requires manual declaration of queues.

**auto_declare** = False

class Exchange(name=", type=", channel=None, **kwargs)

An Exchange declaration.

**Parameters**

- **name** *(str)*  – See *name*.
- **type** *(str)*  – See *type*.
- **channel** *(kombu.Connection, ChannelT)*  – See *channel*.
- **durable** *(bool)*  – See *durable*.
- **auto_delete** *(bool)*  – See *auto_delete*.
- **delivery_mode** *(enum)*  – See *delivery_mode*.
- **arguments** *(Dict)*  – See *arguments*.
- **no_declare** *(bool)*  – See *no_declare*

**name**

Name of the exchange. Default is no name (the default exchange).

**Type** *str*

**type**

*This description of AMQP exchange types was shamelessly stolen from the blog post ‘AMQP in 10 minutes: Part 4’ by Rajith Attapattu. Reading this article is recommended if you’re new to amqp.***

“AMQP defines four default exchange types (routing algorithms) that covers most of the common messaging use cases. An AMQP broker can also define additional exchange types, so see your broker manual for more information about available exchange types.

- **direct** *(default)*

  Direct match between the routing key in the message, and the routing criteria used when a queue is bound to this exchange.

- **topic**

  Wildcard match between the routing key and the routing pattern specified in the exchange/queue binding. The routing key is treated as zero or more words delimited by ‘.’ and supports special wildcard characters. “*” matches a single word and “#” matches zero or more words.

- **fanout**

3.12. Internals
Queues are bound to this exchange with no arguments. Hence any message sent to this exchange will be forwarded to all queues bound to this exchange.

- **headers**

  Queues are bound to this exchange with a table of arguments containing headers and values (optional). A special argument named “x-match” determines the matching algorithm, where “all” implies an AND (all pairs must match) and “any” implies OR (at least one pair must match).

  arguments is used to specify the arguments.

  **Type** str

  **channel**

  The channel the exchange is bound to (if bound).

  **Type** ChannelT

  **durable**

  Durable exchanges remain active when a server restarts. Non-durable exchanges (transient exchanges) are purged when a server restarts. Default is True.

  **Type** bool

  **auto_delete**

  If set, the exchange is deleted when all queues have finished using it. Default is False.

  **Type** bool

  **delivery_mode**

  The default delivery mode used for messages. The value is an integer, or alias string.

  - 1 or “transient”
    
    The message is transient. Which means it is stored in memory only, and is lost if the server dies or restarts.

  - 2 or “persistent” (default)

    The message is persistent. Which means the message is stored both in-memory, and on disk, and therefore preserved if the server dies or restarts.

    The default value is 2 (persistent).

  **Type** enum

  **arguments**

  Additional arguments to specify when the exchange is declared.

  **Type** Dict

  **no_declare**

  Never declare this exchange (declare() does nothing).

  **Type** bool

  **Message** (body, delivery_mode=None, properties=None, **kwargs)

  Create message instance to be sent with publish().

  **Parameters**

  - **body** (Any) – Message body.

  - **delivery_mode** (bool) – Set custom delivery mode. Defaults to delivery_mode.

  - **priority** (int) – Message priority, 0 to broker configured max priority, where higher is better.

  - **content_type** (str) – The messages content_type. If content_type is set, no serialization occurs as it is assumed this is either a binary ob-
ject, or you’ve done your own serialization. Leave blank if using built-in serialization as our library properly sets content_type.

- **content_encoding** *(str)* – The character set in which this object is encoded. Use “binary” if sending in raw binary objects. Leave blank if using built-in serialization as our library properly sets content_encoding.

- **properties** *(Dict)* – Message properties.

- **headers** *(Dict)* – Message headers.

PERSISTENT_DELIVERY_MODE = 2

TRANSIENT_DELIVERY_MODE = 1

attrs = (('name', None), ('type', None), ('arguments', None), ('durable', bool), ('passive', bool), ('auto_delete', bool), ('delivery_mode', function Exchange.<lambda>), ('no_declare', bool))

auto_delete = False

bind_to(exchange=''', routing_key=''', arguments=None, nowait=False, channel=None, **kwargs)

Bind the exchange to another exchange.

Parameters

nowait (bool) – If set the server will not respond, and the call will not block waiting for a response. Default is False.

binding(routing_key=''', arguments=None, unbind_arguments=None)

can_cache_declaration

bool(x) -> bool

Returns True when the argument x is true, False otherwise. The builtins True and False are the only two instances of the class bool. The class bool is a subclass of the class int, and cannot be subclassed.

declare(nowait=False, passive=None, channel=None)

Declare the exchange.

Creates the exchange on the broker, unless passive is set in which case it will only assert that the exchange exists.

Argument:

nowait (bool): If set the server will not respond, and a response will not be waited for. Default is False.

delete(if_unused=False, nowait=False)

Delete the exchange declaration on server.

Parameters

- if_unused (bool) – Delete only if the exchange has no bindings. Default is False.

- nowait (bool) – If set the server will not respond, and a response will not be waited for. Default is False.

delivery_mode = None

durable = True

name = ''

no_declare = False

passive = False

publish(message, routing_key=None, mandatory=False, immediate=False, exchange=None)

Publish message.
Parameters

- **message** \(\text{Union}[\text{kombu.Message}, \text{str}, \text{bytes}]\) – Message to publish.
- **routing_key** \(\text{str}\) – Message routing key.
- **mandatory** \(\text{bool}\) – Currently not supported.
- **immediate** \(\text{bool}\) – Currently not supported.

```python
type = 'direct'
```

```python
unbind_from(source='.', routing_key='.', nowait=False, arguments=None, channel=None)
```
Delete previously created exchange binding from the server.

```python
class Producer(channel, exchange=None, routing_key=None, serializer=None, auto_declare=None, compression=None, on_return=None)
```
Message Producer.

Parameters

- **channel** \(\text{kombu.Connection, ChannelT}\) – Connection or channel.
- **exchange** \(\text{kombu.entity.Exchange, str}\) – Optional default exchange.
- **routing_key** \(\text{str}\) – Optional default routing key.
- **serializer** \(\text{str}\) – Default serializer. Default is “json”.
- **compression** \(\text{str}\) – Default compression method. Default is no compression.
- **auto_declare** \(\text{bool}\) – Automatically declare the default exchange at instantiation. Default is `True`.
- **on_return** \(\text{Callable}\) – Callback to call for undeliverable messages, when the `mandatory` or `immediate` arguments to `publish()` is used. This callback needs the following signature: `(exception, exchange, routing_key, message)`. Note that the producer needs to drain events to use this feature.

```python
autoDeclare = True
```

```python
channel
close()
```
```
compression = None
connection
declare()
```
Declare the exchange.

**Note:** This happens automatically at instantiation when the `auto_declare` flag is enabled.

```python
exchange = None
```

```python
maybeDeclare(entity, retry=False, **retry_policy)
```
Declare exchange if not already declared during this session.

```python
on_return = None
```

```python
publish(body, routing_key=None, delivery_mode=None, mandatory=False, immediate=False, priority=0, content_type=None, content_encoding=None, serializer=None, headers=None, compression=None, exchange=None, retry=False, retry_policy=None, declare=None, expiration=None, **properties)
```
Publish message to the specified exchange.

Parameters
• **body** (*Any*) – Message body.
• **routing_key** (*str*) – Message routing key.
• **delivery_mode** (*enum*) – See `delivery_mode`.
• **mandatory** (*bool*) – Currently not supported.
• **immediate** (*bool*) – Currently not supported.
• **priority** (*int*) – Message priority. A number between 0 and 9.
• **content_type** (*str*) – Content type. Default is auto-detect.
• **content_encoding** (*str*) – Content encoding. Default is auto-detect.
• **serializer** (*str*) – Serializer to use. Default is auto-detect.
• **compression** (*str*) – Compression method to use. Default is none.
• **headers** (*Dict*) – Mapping of arbitrary headers to pass along with the message body.
• **exchange** (*kombu.entity.Exchange, str*) – Override the exchange. Note that this exchange must have been declared.
• **declare** (*Sequence[EntityT]*) – Optional list of required entities that must have been declared before publishing the message. The entities will be declared using `maybe_declare()`.
• **retry** (*bool*) – Retry publishing, or declaring entities if the connection is lost.
• **retry_policy** (*Dict*) – Retry configuration, this is the keywords supported by `ensure()`.
• **expiration** (*float*) – A TTL in seconds can be specified per message. Default is no expiration.
• **properties** (*Any*) – Additional message properties, see AMQP spec.

```python
release()
```

```python
revive(channel)
```
Revive the producer after connection loss.

```python
routing_key = '
serializer = None
```

class Queue (**kwargs**)
Queue that never caches declaration.

can_cache_declaration = False
class ResultConsumer (**kwargs**)

class Consumer (**kwargs**)
Message consumer.

Parameters

• **channel** (*kombu.Connection, ChannelT*) – see channel.
• **queues** *(Sequence[kombu.Queue]) – see queues.*
• **no_ack** *(bool) – see no_ack.*
• **autoDeclare** *(bool) – see auto_declare*
• **callbacks** *(Sequence[Callable]) – see callbacks.*
• **onMessage** *(Callable) – See on_message*
• **onDecodeError** *(Callable) – see on_decode_error.*
• **prefetchCount** *(int) – see prefetch_count.*

**exception ContentDisallowed**
Consumer does not allow this content-type.

**accept = None**

**add_queue** *(queue)*
Add a queue to the list of queues to consume from.

---

**Note:** This will not start consuming from the queue, for that you will have to call **consume()** after.

**autoDeclare = True**

**callbacks = None**

**cancel** ()
End all active queue consumers.

---

**Note:** This does not affect already delivered messages, but it does mean the server will not send any more messages for this consumer.

**cancelByQueue** *(queue)*
Cancel consumer by queue name.

**channel = None**

**close** ()
End all active queue consumers.

---

**Note:** This does not affect already delivered messages, but it does mean the server will not send any more messages for this consumer.

**connection**

**consume** *(no_ack= None)*
Start consuming messages.

Can be called multiple times, but note that while it will consume from new queues added since the last call, it will not cancel consuming from removed queues (use **cancelByQueue()**).

**Parameters**

**no_ack** *(bool) – See no_ack.*

**consumingFrom** *(queue)*
Return True if currently consuming from queue’.
declare()
Declare queues, exchanges and bindings.

**Note:** This is done automatically at instantiation when `auto_declare` is set.

flow (**active**)  
Enable/disable flow from peer.
This is a simple flow-control mechanism that a peer can use to avoid overflowing its queues or otherwise finding itself receiving more messages than it can process.
The peer that receives a request to stop sending content will finish sending the current content (if any), and then wait until flow is reactivated.

```python
no_ack = None
on_decode_error = None
on_message = None
```

prefetch_count = None

**purge**()
Purge messages from all queues.

**Warning:** This will delete all ready messages, there is no undo operation.

```python
qos (prefetch_size=0, prefetch_count=0, apply_global=False)
```
Specify quality of service.
The client can request that messages should be sent in advance so that when the client finishes processing a message, the following message is already held locally, rather than needing to be sent down the channel. Prefetching gives a performance improvement.
The prefetch window is Ignored if the `no_ack` option is set.

**Parameters**

- `prefetch_size (int)` – Specify the prefetch window in octets.
The server will send a message in advance if it is equal to or smaller in size than the available prefetch size (and also falls within other prefetch limits). May be set to zero, meaning “no specific limit”, although other prefetch limits may still apply.

- `prefetch_count (int)` – Specify the prefetch window in terms of whole messages.

- `apply_global (bool)` – Apply new settings globally on all channels.

```python
queues
```

**receive (body, message)**
Method called when a message is received.
This dispatches to the registered `callbacks`.

**Parameters**

- `body (Any)` – The decoded message body.

- `message (Message)` – The message instance.
**Raises** `NotImplementedError` – If no consumer callbacks have been registered.

**recover**(requeue=False)

Redeliver unacknowledged messages.

Asks the broker to redeliver all unacknowledged messages on the specified channel.

**Parameters** requeue (bool) – By default the messages will be redelivered to the original recipient. With requeue set to true, the server will attempt to requeue the message, potentially then delivering it to an alternative subscriber.

**register_callback**(callback)

Register a new callback to be called when a message is received.

---

**Note:** The signature of the callback needs to accept two arguments: `(body, message)`, which is the decoded message body and the `Message` instance.

**revive**(channel)

Revive consumer after connection loss.

cancel_for(task_id)

custom_from(task_id)

drain_events(timeout=None)

on_after_fork()

start(initial_task_id, no_ack=True, **kwargs)

stop()

as_uri(include_password=True)

Return the backend as an URI, sanitizing the password or not.

binding

delete_group(group_id)

destination_for(task_id, request)

Get the destination for result by task id.

Returns tuple of `(reply_to, correlation_id)`.

Return type `Tuple[str, str]`

ensure_chords_allowed()

get_task_meta(task_id, backlog_limit=1000)

oid

on_out_of_band_result(task_id, message)

on_reply_declare(task_id)

on_result_fulfilled(result)

on_task_call(producer, task_id)

persistent = False

poll(task_id, backlog_limit=1000)
reload_group_result (task_id)
    Reload group result, even if it has been previously fetched.

reload_task_result (task_id)
    Reload task result, even if it has been previously fetched.

restore_group (group_id, cache=True)
    Get the result for a group.

retry_policy = {'interval_max': 1, 'interval_start': 0, 'interval_step': 1, 'max_retries': 20}

revive (channel)

save_group (group_id, result)
    Store the result of an executed group.

store_result (task_id, result, state, traceback=None, request=None, **kwargs)
    Send task return value and state.

supports_autoexpire = True

supports_native_join = True

celery.backends.database

SQLAlchemy result store backend.

class celery.backends.database.DatabaseBackend (dburi=None, engine_options=None, url=None, **kwargs)
    The database result backend.

    ResultSession (session_manager=<celery.backends.database.session.SessionManager object>)

    cleanup ()
        Delete expired meta-data.

    extended_result

    subpolling_interval = 0.5

    task_cls
        alias of celery.backends.database.models.Task

    taskset_cls
        alias of celery.backends.database.models.TaskSet

celery.backends.amqp

The old AMQP result backend, deprecated and replaced by the RPC backend.

exception celery.backends.amqp.BacklogLimitExceeded
    Too much state history to fast-forward.

class celery.backends.amqp.AMQPBackend (app, connection=None, exchange=None, exchange_type=None, persistent=None, serializer=None, auto_delete=True, **kwargs)
    The AMQP result backend.

    Deprecated: Please use the RPC backend or a persistent backend.

exception BacklogLimitExceeded
    Too much state history to fast-forward.
class Consumer\(\) (\(channel, \text{\texttt{queues=}}\text{None}, \text{\texttt{no_ack=}}\text{None}, \text{\texttt{auto_declare=}}\text{None}, \text{\texttt{callbacks=}}\text{None}, \text{\texttt{on_decode_error=}}\text{None}, \text{\texttt{on_message=}}\text{None}, \text{\texttt{accept=}}\text{None}, \text{\texttt{prefetch_count=}}\text{None}, \text{\texttt{tag_prefix=}}\text{None})\)

Message consumer.

**Parameters**

- `channel` (``kombu.Connection, ChannelT``) – see `channel`.
- `queues` (``Sequence[kombu.Queue]``) – see `queues`.
- `no_ack` (``bool``) – see `no_ack`.
- `auto_declare` (``bool``) – see `auto_declare`
- `callbacks` (``Sequence[Callable]``) – see `callbacks`.
- `on_message` (``Callable``) – See `on_message`
- `on_decode_error` (``Callable``) – see `on_decode_error`.
- `prefetch_count` (``int``) – see `prefetch_count`.

**exception ContentDisallowed**

Consumer does not allow this content-type.

``accept = None``

**add_queue** (``queue``)

Add a queue to the list of queues to consume from.

**Note:** This will not start consuming from the queue, for that you will have to call `consume()` after.

``auto_declare = True``

``callbacks = None``

**cancel()**

End all active queue consumers.

**Note:** This does not affect already delivered messages, but it does mean the server will not send any more messages for this consumer.

``cancel_by_queue`` (``queue``)

Cancel consumer by queue name.

``channel = None``

**close()**

End all active queue consumers.

**Note:** This does not affect already delivered messages, but it does mean the server will not send any more messages for this consumer.

``connection``

**consume** (``no_ack=None``)

Start consuming messages.

Can be called multiple times, but note that while it will consume from new queues added since the last call, it will not cancel consuming from removed queues (use `cancel_by_queue()`).

**Parameters**

- `no_ack` (``bool``) – See `no_ack`.

**consuming_from** (``queue``)

Return `True` if currently consuming from queue’.
**declare**

Declare queues, exchanges and bindings.

---

**Note:** This is done automatically at instantiation when `auto_declare` is set.

**flow** *(active)*

Enable/disable flow from peer.

This is a simple flow-control mechanism that a peer can use to avoid overflowing its queues or otherwise finding itself receiving more messages than it can process.

The peer that receives a request to stop sending content will finish sending the current content (if any), and then wait until flow is reactivated.

**no_ack** = `None`

**on_decode_error** = `None`

**on_message** = `None`

**prefetch_count** = `None`

**purge**

Purge messages from all queues.

---

**Warning:** This will delete all ready messages, there is no undo operation.

**qos** *(prefetch_size=0, prefetch_count=0, apply_global=False)*

Specify quality of service.

The client can request that messages should be sent in advance so that when the client finishes processing a message, the following message is already held locally, rather than needing to be sent down the channel. Prefetching gives a performance improvement.

The prefetch window is ignored if the **no_ack** option is set.

**Parameters**

- **prefetch_size** *(int)* – Specify the prefetch window in octets. The server will send a message in advance if it is equal to or smaller in size than the available prefetch size (and also falls within other prefetch limits). May be set to zero, meaning “no specific limit”, although other prefetch limits may still apply.

- **prefetch_count** *(int)* – Specify the prefetch window in terms of whole messages.

- **apply_global** *(bool)* – Apply new settings globally on all channels.

**queues**

**receive** *(body, message)*

Method called when a message is received.

This dispatches to the registered callbacks.

**Parameters**

- **body** *(Any)* – The decoded message body.

- **message** *(Message)* – The message instance.

**Raises** `NotImplementedError` – If no consumer callbacks have been registered.
**recover** *(requeue=False)*

Redeliver unacknowledged messages.

Asks the broker to redeliver all unacknowledged messages on the specified channel.

**Parameters**

- **requeue** *(bool)* — By default the messages will be redelivered to the original recipient. With *requeue* set to true, the server will attempt to requeue the message, potentially then delivering it to an alternative subscriber.

**register_callback** *(callback)*

Register a new callback to be called when a message is received.

**Note:** The signature of the callback needs to accept two arguments: *(body, message)*, which is the decoded message body and the *Message* instance.

**revive** *(channel)*

Revive consumer after connection loss.

**class Exchange**(name=", type=", channel=None, **kwargs)

An Exchange declaration.

**Parameters**

- **name** *(str)* — See name.
- **type** *(str)* — See type.
- **channel** *(kombu.Connection, ChannelT)* — See channel.
- **durable** *(bool)* — See durable.
- **auto_delete** *(bool)* — See auto_delete.
- **delivery_mode** *(enum)* — See delivery_mode.
- **arguments** *(Dict)* — See arguments.
- **no_declare** *(bool)* — See no_declare

**name**

Name of the exchange. Default is no name (the default exchange).

**Type** *str*

**type**

*This description of AMQP exchange types was shamelessly stolen from the blog post ‘AMQP in 10 minutes: Part 4’ by Rajith Attapattu. Reading this article is recommended if you’re new to amqp.*

“AMQP defines four default exchange types (routing algorithms) that covers most of the common messaging use cases. An AMQP broker can also define additional exchange types, so see your broker manual for more information about available exchange types.

- **direct** *(default)*

  Direct match between the routing key in the message, and the routing criteria used when a queue is bound to this exchange.

- **topic**

  Wildcard match between the routing key and the routing pattern specified in the exchange/queue binding. The routing key is treated as zero or more words delimited by ‘.’ and supports special wildcard characters. ‘*’ matches a single word and ‘#’ matches zero or more words.

- **fanout**

  Queues are bound to this exchange with no arguments. Hence any message sent to this exchange will be forwarded to all queues bound to this exchange.

- **headers**
Queues are bound to this exchange with a table of arguments containing headers and values (optional). A special argument named “x-match” determines the matching algorithm, where “all” implies an AND (all pairs must match) and “any” implies OR (at least one pair must match).

`arguments` is used to specify the arguments.

- **channel**
  - The channel the exchange is bound to (if bound).
  - Type: `ChannelT`

- **durable**
  - Durable exchanges remain active when a server restarts. Non-durable exchanges (transient exchanges) are purged when a server restarts. Default is `True`.
  - Type: `bool`

- **auto_delete**
  - If set, the exchange is deleted when all queues have finished using it. Default is `False`.
  - Type: `bool`

- **delivery_mode**
  - The default delivery mode used for messages. The value is an integer, or alias string.
    - 1 or “`transient`”
      - The message is transient. Which means it is stored in memory only, and is lost if the server dies or restarts.
    - 2 or “`persistent`” (default)
      - The message is persistent. Which means the message is stored both in-memory, and on disk, and therefore preserved if the server dies or restarts.
  - The default value is 2 (persistent).
  - Type: `enum`

- **arguments**
  - Additional arguments to specify when the exchange is declared.
  - Type: `Dict`

- **no_declare**
  - Never declare this exchange (`declare()` does nothing).
  - Type: `bool`

- **Message**
  - Create message instance to be sent with `publish()`.
  - Parameters
    - **body** *(Any)* – Message body.
    - **delivery_mode** *(bool)* – Set custom delivery mode. Defaults to `delivery_mode`.
    - **priority** *(int)* – Message priority, 0 to broker configured max priority, where higher is better.
    - **content_type** *(str)* – The messages content_type. If content_type is set, no serialization occurs as it is assumed this is either a binary object, or you’ve done your own serialization. Leave blank if using built-in serialization as our library properly sets content_type.
    - **content_encoding** *(str)* – The character set in which this object is encoded. Use “binary” if sending in raw binary objects. Leave blank if using built-in serialization as our library properly sets content_encoding.
• **properties** (*Dict*) – Message properties.

• **headers** (*Dict*) – Message headers.

```
PERSISTENT_DELIVERY_MODE = 2
TRANSIENT_DELIVERY_MODE = 1
```

```
attrs = (('name', None), ('type', None), ('arguments', None), ('durable', <class 'bool'>), ('passive', <class 'bool'>), ('auto_delete', <class 'bool'>), ('delivery_mode', <function Exchange.<lambda>>), ('no_declare', <class 'bool'>))
```

```
auto_delete = False
```

```
bind_to (exchange='', routing_key='', arguments=None, nowait=False, channel=None, **kwargs)

   Bind the exchange to another exchange.

   Parameters
   nowait (bool) – If set the server will not respond, and the call will not
   block waiting for a response. Default is False.
```

```
binding (routing_key='', arguments=None, unbind_arguments=None)
```

```
can_cache_declaration

   bool(x) -> bool

   Returns True when the argument x is true, False otherwise. The builtins True and False are the
   only two instances of the class bool. The class bool is a subclass of the class int, and cannot be
   subclassed.
```

```
declare (nowait=False, passive=None, channel=None)

   Declare the exchange.

   Creates the exchange on the broker, unless passive is set in which case it will only assert that the
   exchange exists.

   Argument:
   nowait (bool): If set the server will not respond, and a response will not be waited for. Default is False.
```

```
delete (if_unused=False, nowait=False)

   Delete the exchange declaration on server.

   Parameters
   • if_unused (bool) – Delete only if the exchange has no bindings. Default is False.
   • nowait (bool) – If set the server will not respond, and a response will not be waited for. Default is False.
```

```
delivery_mode = None
durable = True
name = ''
noDeclare = False
passive = False
```

```
publish (message, routing_key=None, mandatory=False, immediate=False, exchange=None)

   Publish message.

   Parameters
   • message (Union[kombu.Message, str, bytes]) – Message to publish.
   • routing_key (str) – Message routing key.
   • mandatory (bool) – Currently not supported.
```
Celery Documentation, Release 4.4.0

- immediate (bool) – Currently not supported.

```python
immediate (bool) – Currently not supported.
```

```python
type = 'direct'
```

```python
unbind_from (source=", routing_key=", nowait=False, arguments=None, channel=None)
```

Delete previously created exchange binding from the server.

```python
class Producer(channel, exchange=None, routing_key=None, serializer=None, auto_declare=None, compression=None, on_return=None)
```

Message Producer.

Parameters
- channel (kombu.Connection, ChannelT) – Connection or channel.
- exchange (kombu.entity.Exchange, str) – Optional default exchange.
- routing_key (str) – Optional default routing key.
- serializer (str) – Default serializer. Default is “json”.
- compression (str) – Default compression method. Default is no compression.
- auto_declare (bool) – Automatically declare the default exchange at instantiation. Default is True.
- on_return (Callable) – Callback to call for undeliverable messages, when the mandatory or immediate arguments to publish() is used. This callback needs the following signature: (exception, exchange, routing_key, message). Note that the producer needs to drain events to use this feature.

```python
auto_declare = True
```

```python
channel
close()
```

```python
compression = None
```

```python
connection
declare()
```

Declare the exchange.

```
Note: This happens automatically at instantiation when the auto_declare flag is enabled.
```

```python
exchange = None
```

```python
maybe_declare (entity, retry=False, **retry_policy)
```

Declare exchange if not already declared during this session.

```python
on_return = None
```

```python
publish (body, routing_key=None, delivery_mode=None, mandatory=False, immediate=False, priority=0, content_type=None, content_encoding=None, serializer=None, headers=None, compression=None, exchange=None, retry=False, retry_policy=None, declare=None, expiration=None, **properties)
```

Publish message to the specified exchange.

Parameters
- body (Any) – Message body.
- routing_key (str) – Message routing key.
- delivery_mode (enum) – See delivery_mode.
- mandatory (bool) – Currently not supported.
• **immediate** *(bool)* – Currently not supported.
• **priority** *(int)* – Message priority. A number between 0 and 9.
• **content_type** *(str)* – Content type. Default is auto-detect.
• **content_encoding** *(str)* – Content encoding. Default is auto-detect.
• **serializer** *(str)* – Serializer to use. Default is auto-detect.
• **compression** *(str)* – Compression method to use. Default is none.
• **headers** *(Dict)* – Mapping of arbitrary headers to pass along with the message body.
• **exchange** *(kombu.entity.Exchange, str)* – Override the exchange. Note that this exchange must have been declared.
• **declare** *(Sequence[EntityT])* – Optional list of required entities that must have been declared before publishing the message. The entities will be declared using `maybe_declare()`.
• **retry** *(bool)* – Retry publishing, or declaring entities if the connection is lost.
• **retry_policy** *(Dict)* – Retry configuration, this is the keywords supported by `ensure()`.
• **expiration** *(float)* – A TTL in seconds can be specified per message. Default is no expiration.
• ****properties** *(Any)* – Additional message properties, see AMQP spec.

```python
release()
revive(channel)
    Revive the producer after connection loss.

routing_key = ''
serializer = None

Queue
    alias of NoCacheQueue

as_uri(include_password=True)
    Return the backend as an URI, sanitizing the password or not.

consume(task_id, timeout=None, no_ack=True, on_interval=None)

delete_group(group_id)

destination_for(task_id, request)

drain_events(connection, consumer, timeout=None, on_interval=None, now=<built-in function monotonic>, wait=None)

get_many(task_ids, timeout=None, no_ack=True, on_message=None, on_interval=None, now=<built-in function monotonic>, getfields=operator.itemgetter('status', 'task_id'), READY_STATES=frozenset(['FAILURE', 'REVOKED', 'SUCCESS']), PROPAGATE_STATES=frozenset(['FAILURE', 'REVOKED']), **kwargs)

get_task_meta(task_id, backlog_limit=1000)

on_reply_declare(task_id)
```
persistent = True

poll (task_id, backlog_limit=1000)

reload_group_result (task_id)
Reload group result, even if it has been previously fetched.

reload_task_result (task_id)
Reload task result, even if it has been previously fetched.

restore_group (group_id, cache=True)
Get the result for a group.

retry_policy = {'interval_max': 1, 'interval_start': 0, 'interval_step': 1, 'max_retries': 20

revive (channel)

rkey (task_id)

save_group (group_id, result)
Store the result of an executed group.

store_result (task_id, result, state, traceback=None, request=None, **kwargs)
Send task return value and state.

supports_autoexpire = True

supports_native_join = True

wait_for (task_id, timeout=None, cache=True, no_ack=True, on_interval=None, READY_STATES=frozenset({'FAILURE', 'REVOKED', 'SUCCESS'}), PROPAGATE_STATES=frozenset({'FAILURE', 'REVOKED'}), **kwargs)
Wait for task and return its result.

If the task raises an exception, this exception will be re-raised by wait_for().
Raises celery.exceptions.TimeoutError – If timeout is not None, and the operation takes longer than timeout seconds.

celery.backends.cache

Memcached and in-memory cache result backend.

class celery.backends.cache.CacheBackend (app, expires=None, backend=None, options=None, url=None, **kwargs)
Cache result backend.

as_uri (*args, **kwargs)
Return the backend as an URI.

This properly handles the case of multiple servers.

client
delete (key)
expire (key, value)
get (key)

implements_incr = True

incr (key)
mget (keys)
servers = None
Celery Documentation, Release 4.4.0

```python
set(key, value)
supports_autoexpire = True
supports_native_join = True
```

celery.backends.consul

Consul result store backend.

- `ConsulBackend` implements `KeyValueStoreBackend` to store results in the key-value store of Consul.

class celery.backends.consul.ConsulBackend(*args, **kwargs)

    Consul.io K/V store backend for Celery.

    ```python
    client = None
    consistency = 'consistent'
    consul = None
    delete(key)
    get(key)
    mget(keys)
    path = None
    set(key, value)
        Set a key in Consul.
        Before creating the key it will create a session inside Consul where it creates a session with a TTL.
        The key created afterwards will reference to the session’s ID.
        If the session expires it will remove the key so that results can auto expire from the K/V store.
    ```

```
supports_autoexpire = True
```

celery.backends.couchdb

CouchDB result store backend.

class celery.backends.couchdb.CouchBackend(url=None, *args, **kwargs)

    CouchDB backend.

    Raises `celery.exceptions.ImproperlyConfigured` – if module `pycouchdb` is not available.

    ```python
    connection
    container = 'default'
    delete(key)
    get(key)
    host = 'localhost'
    mget(keys)
    password = None
    port = 5984
    scheme = 'http'
    ```
set(key, value)
username = None

celery.backends.mongodb

MongoDB result store backend.
class celery.backends.mongodb.MongoBackend(app=None, **kwargs)
    MongoDB result backend.
    Raises celery.exceptions.ImproperlyConfigured – if module pymongo is not available.
    as_uri(include_password=False)
        Return the backend as an URI.
        Parameters include_password=bool – Password censored if disabled.
cleanup()
    Delete expired meta-data.
collection
    Get the meta-data task collection.
database
    Get database from MongoDB connection.
    performs authentication if necessary.
database_name = 'celery'
delete(data)
cencode(data)
expires_delta
group_collection
    Get the meta-data task collection.
groupmeta_collection = 'celery_groupmeta'
host = 'localhost'
max_pool_size = 10
mongo_host = None
options = None
password = None
port = 27017
supports_autoexpire = False
taskmeta_collection = 'celery_taskmeta'
user = None

celery.backends.elasticsearch

Elasticsearch result store backend.
class celery.backends.elasticsearch.ElasticsearchBackend(url=None, *args, **kwargs)

Elasticsearch Backend.
Raises celery.exceptions.ImproperlyConfigured – if module elasticsearch is not available.
delete(key)
doc_type = 'backend'
es_max_retries = 3
es_retry_on_timeout = False
es_timeout = 10
get(key)
host = 'localhost'
index = 'celery'
mget(keys)
password = None
port = 9200
scheme = 'http'
server
set(key, value)
username = None

celery.backends.redis

Redis result store backend.
class celery.backends.redis.RedisBackend(host=None, port=None, db=None, password=None, max_connections=None, url=None, connection_pool=None, **kwargs)

Redis task result store.
It makes use of the following commands: GET, MGET, DEL, INCRBY, EXPIRE, SET, SETEX

ConnectionPool
class ResultConsumer(*args, **kwargs)

cancel_for(task_id)
consume_from(task_id)
drain_events(timeout=None)
on_after_fork()
on_state_change(meta, message)
on_wait_for_pending(result, **kwargs)
start(initial_task_id, **kwargs)
stop()
add_to_chord(group_id, result)
apply_chord(header_result, body, **kwargs)
client
db
delete(key)
ensure(fun, args, **policy)
expire(key, value)
forget(task_id)
get(key)
host
incr(key)
max_connections = None
  Maximum number of connections in the pool.
mget(keys)
on_chord_part_return(request, state, result, propagate=None, **kwargs)
on_connection_error(max_retries, exc, intervals, retries)
on_task_call(producer, task_id)
password
port
redis = None
  redis client module.
supports_autoexpire = True
supports_native_join = True
class celery.backends.redis.SentinelBackend(*args, **kwargs)
  Redis sentinel task result store.
  sentinel = None

celery.backends.riak

Riak result store backend.
class celery.backends.riak.RiakBackend(host=None, port=None, bucket_name=None, protocol=None, url=None, *args, **kwargs)
  Riak result backend.
  Raises celery.exceptions.ImproperlyConfigured – if module riak is not available.
bucket
bucket_name = 'celery'
  default Riak bucket name (default)
client
delete(key)
get (key)

host = 'localhost'
    default Riak server hostname (localhost)

mget (keys)

port = 8087
    default Riak server port (8087)

protocol = 'pbc'
    default protocol used to connect to Riak, might be http or pbc

set (key, value)

celery.backends.cassandra

Apache Cassandra result store backend using the DataStax driver.

class celery.backends.cassandra.CassandraBackend (servers=None,   
    keyspace=None,   
    table=None,   
    entry_ttl=None,   
    port=9042, **kwargs)

    Cassandra backend utilizing DataStax driver.
    
    Raises celery.exceptions.ImproperlyConfigured – if module cassandra-driver is not available, or if the cassandra_servers setting is not set.

    as_uri (include_password=True)
        Return the backend as an URI, sanitizing the password or not.

    process_cleanup ()
        Cleanup actions to do at the end of a task worker process.

    servers = None
        hostname.
        
        Type List of Cassandra servers with format

    supports_autoexpire = True

celery.backends.couchbase

Couchbase result store backend.

class celery.backends.couchbase.CouchbaseBackend (url=None, *args, **kwargs)

    Couchbase backend.
    
    Raises celery.exceptions.ImproperlyConfigured – if module couchbase is not available.

    bucket = 'default'

    connection

    delete (key)

    get (key)

    host = 'localhost'

    key_t
        alias of builtins.str

    mget (keys)

    password = None
Celery Documentation, Release 4.4.0

port = 8091
quiet = False

set(key, value)
supports_autoexpire = True
timeout = 2.5
username = None

celery.backends.arangodb

ArangoDb result store backend.
class celery.backends.arangodb.ArangoDbBackend(url=None, args, **kwargs)
   ArangoDb backend.
   Sample url “arangodb://username:password@host:port/database/collection” arangodb_backend_settings is where the settings are present (in the app.conf) Settings should contain the host, port, username, password, database name, collection name else the default will be chosen. Default database name and collection name is celery.
   Raises celery.exceptions.ImproperlyConfigured: – if module pyArango is not available.
collection = 'celery'
connection
   Connect to the arangodb server.
database = 'celery'
db
   Database Object to the given database.
delete(key)
get(key)
host = '127.0.0.1'
http_protocol = 'http'
key_t
   alias of builtins.str
mget(keys)
password = None
port = '8529'
set(key, value)
   Insert a doc with value into task attribute and _key as key.
username = None

celery.backends.dynamodb

AWS DynamoDB result store backend.
class celery.backends.dynamodb.DynamoDBBackend(url=None, table_name=None, args, **kwargs)
   AWS DynamoDB result backend.
Raises `celery.exceptions.ImproperlyConfigured` – if module `boto3` is not available.

```python/aws_region = None
AWS region (default)
```

```python
client
```

```python
delete(key)
```

```python
endpoint_url = None
The endpoint URL that is passed to boto3 (local DynamoDB) (default)
```

```python
get(key)
```

```python
mget(keys)
```

```python
read_capacity_units = 1
Read Provisioned Throughput (default)
```

```python
set(key, value)
```

```python
supports_autoexpire = True
```

```python
table_name = 'celery'
default DynamoDB table name (default)
```

```python
time_to_live_seconds = None
Item time-to-live in seconds (default)
```

```python
write_capacity_units = 1
Write Provisioned Throughput (default)
```

**celery.backends.filesystem**

File-system result store backend.

```python
class celery.backends.filesystem.FilesystemBackend(url=None, open=<built-in function open>, unlink=<built-in function unlink>, sep='/', encoding='UTF-8', *args, **kwargs)
```

File-system result backend.

**Parameters**

- `url (str)` – URL to the directory we should use
- `open (Callable)` – open function to use when opening files
- `unlink (Callable)` – unlink function to use when deleting files
- `sep (str)` – directory separator (to join the directory with the key)
- `encoding (str)` – encoding used on the file-system

```python
delete(key)
```

```python
get(key)
```

```python
mget(keys)
```

```python
set(key, value)
```

**celery.backends.cosmosdbsql**

The CosmosDB/SQL backend for Celery (experimental).
class celery.backends.cosmosdbsql.CosmosDBSQLBackend(url=None, database_name=None, collection_name=None, consistency_level=None, max_retry_attempts=None, max_retry_wait_time=None, *args, **kwargs)

CosmosDB/SQL backend for Celery.

def delete(key)
    Delete the value at a given key.
    Parameters key – The key of the value to delete.

def get(key)
    Read the value stored at the given key.
    Parameters key – The key for which to read the value.

def mget(keys)
    Read all the values for the provided keys.
    Parameters keys – The list of keys to read.

def set(key, value)
    Store a value for a given key.
    Parameters
        • key – The key at which to store the value.
        • value – The value to store.

celery.backends.s3

s3 result store backend.

class celery.backends.s3.S3Backend(**kwargs)
    An S3 task result store.
    Raises celery.exceptions.ImproperlyConfigured – if module boto3 is not available, if the aws_access_key_id or setting aws_secret_access_key are not set, or if the bucket is not set.

def delete(key)

def get(key)

def set(key, value)

celery.app.trace

Trace task execution.

This module defines how the task execution is traced: errors are recorded, handlers are applied and so on.

class celery.app.trace.TraceInfo(state, retval=None)
    Information about task execution.

def handle_error_state(task, req, eager=False, call_errbacks=True)
    Handle exception.

def handle_failure(task, req, store_errors=True, call_errbacks=True)

def handle_ignore(task, req, **kwargs)

def handle_reject(task, req, **kwargs)
**handle_retry** *(task, req, store_errors=True, **kwargs)*

Handle retry exception.

**retval**

**state**

celery.app.trace.build_tracer(*name, task, loader=None, hostname=None, store_errors=True, Info=<class 'celery.app.trace.TracingInfo'>, eager=False, propagate=False, app=None, monotonic=<built-in function monotonic>, trace_ok_t=<class 'celery.app.trace.trace_ok_t'>, IGNORE_STATES=frozenset({'RETRY', 'REJECTED', 'IGNORED'}))

Return a function that traces task execution.

Catches all exceptions and updates result backend with the state and result.

If the call was successful, it saves the result to the task result backend, and sets the task status to “SUCCESS”.

If the call raises *Retry*, it extracts the original exception, uses that as the result and sets the task state to “RETRY”.

If the call results in an exception, it saves the exception as the task result, and sets the task state to “FAILURE”.

Return a function that takes the following arguments:

- **param uuid** The id of the task.
- **param args** List of positional args to pass on to the function.
- **param kwargs** Keyword arguments mapping to pass on to the function.
- **keyword request** Request dict.

celery.app.trace.trace_task(*task, uuid, args, kwargs, request=None, **opts)*

Trace task execution.

celery.app.trace.setup_worker_optimizations(*app, hostname=None)*

Setup worker related optimizations.

celery.app.trace.reset_worker_optimizations()*

Reset previously configured optimizations.

**celery.app.annotations**

Task Annotations.

Annotations is a nice term for monkey-patching task classes in the configuration.

This prepares and performs the annotations in the *task_annotations* setting.

**class** celery.app.annotations.MapAnnotation

Annotation map: task_name => attributes.

**annotate** *(task)*

**annotate_any** ()

celery.app.annotations.prepare(*annotations)*

Expand the *task_annotations* setting.

celery.app.annotations.resolve_all(*anno, task)*

Resolve all pending annotations.
celery.app.routes

Task Routing.
Contains utilities for working with task routers, \(\text{task\_routes}\).

```python
class celery.app.routes.MapRoute(map)
    Creates a router out of a dict.

class celery.app.routes.Router(routes=None, queues=None, create_missing=False, app=None)
    Route tasks based on the task_routes setting.
    expand_destination(route)
    lookup_route(name, args=None, kwargs=None, options=None, task_type=None)
    query_router(router, task, args, kwargs, options, task_type)
    route(options, name, args=(), kwargs=None, task_type=None)

celery.app.routes.prepare(routes)
    Expand the task_routes setting.
```

```
celery.security.certificate

X.509 certificates.
```nn```
class celery.security.certificate.Certificate(cert)
    X.509 certificate.
    get_id()
        Serial number/issuer pair uniquely identifies a certificate.
    get_issuer()
        Return issuer (CA) as a string.
    get_pubkey()
        Get public key from certificate.
    get_serial_number()
        Return the serial number in the certificate.
    has_expired()
        Check if the certificate has expired.
    verify(data, signature, digest)
        Verify signature for string containing data.
```
n```
class celery.security.certificate.CertStore
    Base class for certificate stores.
    add_cert(cert)
    itercerts()
        Return certificate iterator.
```
n```
class celery.security.certificate.FSCertStore(path)
    File system certificate store.
```
celery.security.key

Private keys for the security serializer.

```python
class celery.security.key.PrivateKey(key, password=None)

    Represents a private key.

    sign(data, digest)
    
    Sign string containing data.
```

celery.security.serialization

Secure serializer.

```python
class celery.security.serialization.SecureSerializer(key=None, cert=None, cert_store=None, digest='sha256', serializer='json')

    Signed serializer.

    deserialize(data)
    
    Deserialize data structure from string.

    serialize(data)
    
    Serialize data structure into string.
```

celery.security.serialization.register_auth(key=None, cert=None, store=None, digest='sha256', serializer='json')

Register security serializer.

celery.security.utils

Utilities used by the message signing serializer.

```python
celery.security.utils.get_digest_algorithm(digest='sha256')

    Convert string to hash object of cryptography library.
```

celery.security.utils.reraise_errors(msg='[0!r]', errors=None)

    Context reraising crypto errors as SecurityError.

celery.events.snapshot

Periodically store events in a database.

Consuming the events as a stream isn’t always suitable so this module implements a system to take snapshots of the state of a cluster at regular intervals. There’s a full implementation of this writing the snapshots to a database in `djcelery.snapshots` in the `django-celery` distribution.

```python
class celery.events.snapshot.Polaroid(state, freq=1.0, maxrate=None, cleanup_freq=3600.0, timer=None, app=None)

    Record event snapshots.

    cancel()
    
    capture()

    cleanup()

    cleanup_signal = <Signal: cleanup_signal providing_args=set()>
```
clear_after = False
install()
on_cleanup()
on_shutter(state)
shutter()
shutter_signal = <Signal: shutter_signal providing_args={'state'}>
timer = None
celery.events.snapshot.evcam(camera, freq=1.0, maxrate=None, loglevel=0, logfile=None, pidfile=None, timer=None, app=None)
Start snapshot recorder.

celery.events.cursesmon

Graphical monitor of Celery events using curses.
class celery.events.cursesmon.CursesMonitor(state, app, keymap=None)
A curses based Celery task monitor.

alert(callback, title=None)
alert_remote_control_reply(reply)
background = 7
display_height
display_task_row(lineno, task)
display_width
draw()
find_position()
foreground = 0
format_row(uuid, task, worker, timestamp, state)
greet = 'celery events 4.4.0 (cliffs)'
handle_keypress()
help = 'j:down k:up i:info t:traceback r:result c:revoke ^c: quit'
help_title = 'Keys: '
info_str = 'Info: '
init_screen()
keyaliases = {258: 'J', 259: 'K', 343: 'I'}
keymap = {} 
limit
move_selection(direction=1)
move_selection_down()
move_selection_up()
nap()
online_str = 'Workers online: '  
readline(x, y)
resetscreen()
revoke_selection()
safe_add_str(y, x, string, *args, **kwargs)
screen_delay = 10
screen_height
screen_width
selected_position = 0
selected_str = 'Selected: '
selected_task = None
selection_info()
selection_rate_limit()
selection_result()
selection_traceback()
tasks
win = None
workers
celery.events.cursesmon.evtop(app=None)
    Start curses monitor.

celery.events.dumper
Utility to dump events to screen.
This is a simple program that dumps events to the console as they happen. Think of it like a tcpdump for Celery events.

class celery.events.dumper.Dumper(out=<_io.TextIOWrapper name='<stdout>' mode='w'
                        encoding='UTF-8'>)
    Monitor events.
    format_task_event (hostname, timestamp, type, task, event)
    on_event (ev)
    say(msg)
celery.events.dumper.evdump(app=None, out=<_io.TextIOWrapper name='<stdout>' mode='w'
                        encoding='UTF-8'>)
    Start event dump.
**celery.backends.database.models**

Database models used by the SQLAlchemy result store backend.

```python
class celery.backends.database.models.Task(task_id)
    Task result/status.
    date_done
    id
    result
    status
    task_id
    to_dict()
    traceback

class celery.backends.database.models.TaskExtended(task_id)
    For the extend result.
    args
    date_done
    id
    kwargs
    name
    queue
    result
    retries
    status
    task_id
    to_dict()
    traceback
    worker

class celery.backends.database.models.TaskSet(taskset_id, result)
    TaskSet result.
    date_done
    id
    result
    taskset_id
    to_dict()
```
Celery Documentation, Release 4.4.0

celery.backends.database.session

SQLAlchemy session.

class celery.backends.database.session.SessionManager
    Manage SQLAlchemy sessions.
        create_session(dburi, short_lived_sessions=False, **kwargs)
        get_engine(dburi, **kwargs)
        prepare_models(engine)
        session_factory(dburi, **kwargs)

celery.utils

Utility functions.

Don’t import from here directly anymore, as these are only here for backwards compatibility.

class celery.utils.cached_property (fget=None, fset=None, fdel=None, doc=None)
    Cached property descriptor.
    Caches the return value of the get method on first call.

Examples

```python
@cached_property
def connection(self):
    return Connection()

@connection.setter  # Prepares stored value
def connection(self, value):
    if value is None:
        raise TypeError('Connection must be a connection')
    return value

@connection.deleter
def connection(self, value):
    # Additional action to do at del(self.attr)
    if value is not None:
        print('Connection {0!r} deleted'.format(value))

deleter (fdel)
setter (fset)
```

celery.utils.chunks(it, n)
    Split an iterator into chunks with n elements each.

    Warning: it must be an actual iterator, if you pass this a concrete sequence will get you repeating elements.
    So chunks(iter(range(1000)), 10) is fine, but chunks(range(1000), 10) is not.
Example

```python
# n == 2 >>> x = chunks(iter([0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10]), 2) >>> list(x) [[0, 1], [2, 3], [4, 5], [6, 7], [8, 9], [10]]
# n == 3 >>> x = chunks(iter([0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10]), 3) >>> list(x) [[0, 1, 2], [3, 4, 5], [6, 7, 8], [9, 10]]
```

celery.utils.gen_task_name(app, name, module_name)
Generate task name from name/module pair.

celery.utils.gen_task_name(app, name, module_name)
Generate task name from name/module pair.

celery.utils.gen_unique_id(_uuid=<function uuid4>)
Generate unique id in UUID4 format.

See also:
For now this is provided by uuid.uuid4().

celery.utils.get_cls_by_name(name, aliases=None, imp=None, package=None, sep='.', default=None, **kwargs)
Get symbol by qualified name.
The name should be the full dot-separated path to the class:

```
modulename.ClassName
```

Example:
```
celery.concurrency.processes.TaskPool
   ^- class name
```
or using ‘:’ to separate module and symbol:

```
celery.concurrency.processes:TaskPool
```

If aliases is provided, a dict containing short name/long name mappings, the name is looked up in the aliases first.

Examples

```python
>>> symbol_by_name('celery.concurrency.processes.TaskPool')
<class 'celery.concurrency.processes.TaskPool'>

>>> symbol_by_name('default', {
...   'default': 'celery.concurrency.processes.TaskPool'}
)<class 'celery.concurrency.processes.TaskPool'>

# Does not try to look up non-string names. >>> from celery.concurrency.processes import TaskPool >>> symbol_by_name(TaskPool) is TaskPool True
```

celery.utils.get_full_cls_name(obj)
Return object name.

celery.utils.import_from_cwd(module, imp=None, package=None)
Import module, temporarily including modules in the current directory.

Modules located in the current directory has precedence over modules located in sys.path.
**celery.utils.instantiate** *(name, *args, **kwargs)*

Instantiate class by name.

*See also:*

symbol_by_name()

**celery.utils.memoize** *(maxsize=None, keyfun=None, Cache=kombu.utils.functional.LRUCache)*

Decorator to cache function return value.

**celery.utils.nodename** *(name, hostname)*

Create node name from name/hostname pair.

**celery.utils.nodesplit** *(name)*

Split node name into tuple of name/hostname.

**celery.utils.noop** *(args, **kwargs)*

No operation.

Takes any arguments/keyword arguments and does nothing.

**celery.utils.uuid** *(uuuid=uuid.uuid4)*

Generate unique id in UUID4 format.

*See also:*

For now this is provided by uuid.uuid4().

**celery.utils.worker_direct** *(hostname)*

Return the kombu.Queue being a direct route to a worker.

*Parameters hostname (str, Queue) – The fully qualified node name of a worker (e.g., w1@example.com). If passed a kombu.Queue instance it will simply return that instead.*

## celery.utils.abstract

Abstract classes.

**class celery.utils.abstract.CallableTask**

Task interface.

apply(*args, **kwargs)

apply_async(*args, **kwargs)

delay(*args, **kwargs)

**class celery.utils.abstract.CallableSignature**

Celery Signature interface.

app

args

chord_size

clone(args=None, kwars=None)

freeze(id=None, group_id=None, chord=None, root_id=None)

id

immutable

kwars
Celery Documentation, Release 4.4.0

link(callback)
link_error(errback)
name
options
set(immutable=None, **options)
subtask_type
task
type

celery.utils.collections

Custom maps, sets, sequences, and other data structures.

class celery.utils.collections.AttributeDictMixin
    Mixin for Mapping interface that adds attribute access.
    I.e., d.key -> d[key]).

class celery.utils.collections.AttributeDict
    Dict subclass with attribute access.

class celery.utils.collections.BufferMap(maxsize, iterable=None, bufsize=1000)
    Map of buffers.
    Buffer
        alias of Messagebuffer

    exception Empty
        Exception raised by Queue.get(block=0)/get_nowait().
    bufsize = None
    extend(key, it)
    maxsize = None
    put(key, item)
    take(key, *default)
    total = 0

class celery.utils.collections.ChainMap(*maps, **kwargs)
    Key lookup on a sequence of maps.
    add_defaults(d)
    bind_to(callback)
    changes = None
    clear() → None. Remove all items from D.
    copy()
    defaults = None

    classmethod fromkeys(iterable, *args)
        Create a ChainMap with a single dict created from the iterable.
get \((k, d)\) \(\rightarrow D[k]\) if \(k\) in \(D\), else \(d\). \(d\) defaults to None.

items()

iteritems()

iterkeys()

itervalues()

key_t = None

keys()

maps = None

pop \((k, d)\) \(\rightarrow v\), remove specified key and return the corresponding value.

If key is not found, \(d\) is returned if given, otherwise KeyError is raised.

setdefault \((k, d)\) \(\rightarrow D.get(k,d)\), also set \(D[k]=d\) if \(k\) not in \(D\)

update \((E, **F)\) \(\rightarrow None\). Update \(D\) from mapping/iterable \(E\) and \(F\).

If \(E\) present and has a .keys() method, does: for \(k\) in \(E\): \(D[k] = E[k]\) If \(E\) present and lacks .keys() method, does: for \((k, v)\) in \(E\): \(D[k] = v\) In either case, this is followed by: for \(k, v\) in \(F\).items(): \(D[k] = v\)

values()

class celery.utils.collections.ConfigurationView (changes, defaults=None, keys=None, prefix=None)

A view over an applications configuration dictionaries.

Custom (but older) version of collections.ChainMap.

If the key does not exist in \(changes\), the \(defaults\) dictionaries are consulted.

Parameters

* changes (Mapping) – Map of configuration changes.
* defaults (List [Mapping]) – List of dictionaries containing the default configuration.

clear()

Remove all changes, but keep defaults.

first (*keys)

get \((k, d)\) \(\rightarrow D[k]\) if \(k\) in \(D\), else \(d\). \(d\) defaults to None.

swap_with (other)

class celery.utils.collections.DictAttribute (obj)

Dict interface to attributes.

\(obj[k] -> obj.k \ obj[k] = val \rightarrow obj.k = val\)

get \((key, default=None)\)

items()

iteritems()

iterkeys()

itervalues()

keys()

obj = None

setdefault \((key, default=None)\)
class celery.utils.collections.Evictable
    Mixin for classes supporting the `evict` method.

evict()  # Force evict until maxsize is enforced.

class celery.utils.collections.LimitedSet (maxlen=0, expires=0, data=None, minlen=0)
    Kind-of Set (or priority queue) with limitations.

Good for when you need to test for membership ("a in set"), but the set should not grow unbounded.

`maxlen` is enforced at all times, so if the limit is reached we’ll also remove non-expired items.

You can also configure `minlen`: this is the minimal residual size of the set.

All arguments are optional, and no limits are enabled by default.

Parameters

- `maxlen` (*int*) – Optional max number of items. Adding more items than `maxlen` will result in immediate removal of items sorted by oldest insertion time.
- `expires` (*float*) – TTL for all items. Expired items are purged as keys are inserted.
- `minlen` (*int*) – Minimal residual size of this set. .. versionadded:: 4.0
  Value must be less than `maxlen` if both are configured.

  Older expired items will be deleted, only after the set exceeds `minlen` number of items.
- `data` (*Sequence*) – Initial data to initialize set with. Can be an iterable of (key, value) pairs, a dict (dict(key: insertion_time)), or another instance of `LimitedSet`.

Example

```python
>>> s = LimitedSet(maxlen=50000, expires=3600, minlen=4000)
>>> for i in range(60000):
...     s.add(i)
...     s.add(str(i))
...
>>> 57000 in s  # last 50k inserted values are kept
True
>>> '10' in s  # '10' did expire and was purged from set.
False
>>> len(s)  # maxlen is reached
50000
>>> s.purge(now=monotonic() + 7200)  # clock + 2 hours
>>> len(s)  # now only minlen items are cached
4000
>>> 57000 in s  # even this item is gone now
False
```

```
add(item, now=None)
    Add a new item, or reset the expiry time of an existing item.

as_dict()
    Whole set as serializable dictionary.
```
Example

```python
>>> s = LimitedSet(maxlen=200)
>>> r = LimitedSet(maxlen=200)
>>> for i in range(500):
...    s.add(i)
...    ...
>>> r.update(s.as_dict())
>>> r == s
True
```

clear()
Clear all data, start from scratch again.

discard(item)

max_heap_percent_overload = 15

pop(default=None)
Remove and return the oldest item, or None when empty.

pop_value(item)

purge(now=None)
Check oldest items and remove them if needed.
Parameters

Parameters now (float) – Time of purging – by default right now. This can be useful for unit testing.

update(other)
Update this set from other LimitedSet, dict or iterable.

class celery.utils.collections.Messagebuffer(maxsize, iterable=None, deque=<class 'collections.deque'>)
A buffer of pending messages.

exception Empty
Exception raised by Queue.get(block=0)/get_nowait().

extend(it)

put(item)

take(*default)

class celery.utils.collections.OrderedDict
Dict where insertion order matters.

celery.utils.collections.force_mapping(m)
Wrap object into supporting the mapping interface if necessary.

celery.utils.collections.lpmerge(L, R)
In place left precedent dictionary merge.
    Keeps values from L, if the value in R is None.

celery.utils.nodenames
Worker name utilities.

celery.utils.nodenames.worker_direct(hostname)
Return the kombu.Queue being a direct route to a worker.
Parameters hostname *(str, Queue)* – The fully qualified node name of a worker (e.g., w1@example.com). If passed a `kombu.Queue` instance it will simply return that instead.

celery.utils.nodenames.gethostname() → string
Return the current host name.

celery.utils.nodenames.nodename(name, hostname)
Create node name from name/hostname pair.

celery.utils.nodenames.anon_nodename(hostname=None, prefix='gen')
Return the nodename for this process (not a worker).
This is used for e.g. the origin task message field.

celery.utils.nodenames.nodesplit(name)
Split node name into tuple of name/hostname.

celery.utils.nodenames.default_nodename(hostname)
Return the default nodename for this process.

celery.utils.nodenames.node_format(s, name, **extra)
Format worker node name (name@host.com).

celery.utils.nodenames.host_format(s, host=None, name=None, **extra)
Format host %x abbreviations.

celery.utils.deprecated

Deprecation utilities.

celery.utils.deprecated.Callable(deprecation=None, removal=None, alternative=None, description=None)
Decorator for deprecated functions.

A deprecation warning will be emitted when the function is called.

Parameters

• deprecation *(str)* – Version that marks first deprecation, if this argument isn’t set
  a `PendingDeprecationWarning` will be emitted instead.
• removal *(str)* – Future version when this feature will be removed.
• alternative *(str)* – Instructions for an alternative solution (if any).
• description *(str)* – Description of what’s being deprecated.

celery.utils.deprecated.Property(deprecation=None, removal=None, alternative=None, description=None)
Decorator for deprecated properties.

celery.utils.deprecated.warn(description=None, deprecation=None, removal=None, alternative=None, stacklevel=2)
Warn of (pending) deprecation.

celery.utils.functional

Functional-style utilities.

class celery.utils.functional.LRUCache(limit=None)
LRU Cache implementation using a doubly linked list to track access.

Parameters limit *(int)* – The maximum number of keys to keep in the cache. When a new key
is inserted and the limit has been exceeded, the Least Recently Used key will be discarded
from the cache.

incr(key, delta=1)
items()
iteritems()
iterkeys()
itervalues()
keys()

popitem() \rightarrow (k, v), remove and return some (key, value) pair as a 2-tuple; but raise KeyError if D is empty.

update([E], **F) \rightarrow None. Update D from mapping/iterable E and F.
If E present and has a.keys() method, does: for k in E: D[k] = E[k] If E present and lacks .keys() method, does: for (k, v) in E: D[k] = v
In either case, this is followed by: for k, v in F.items(): D[k] = v

values()
celery.utils.functional.is_list(l, scalars=(<class 'collections.abc.Mapping'>, <class 'str'>),
iters=(<class 'collections.abc.Iterable'>, ))
Return true if the object is iterable.

Note: Returns false if object is a mapping or string.

celery.utils.functional.maybe_list(l, scalars=(<class 'collections.abc.Mapping'>, <class 'str'>))
Return list of one element if l is a scalar.
celery.utils.functional.memoize(maxsize=None, keyfun=None, Cache=<class 'kombu.utils.functional.LRUCache'>)
Decorator to cache function return value.
class celery.utils.functional.mlazy(fun, *args, **kwargs)
Memoized lazy evaluation.
The function is only evaluated once, every subsequent access will return the same value.
evaluate()
evaluated = False
Set to True after the object has been evaluated.
celery.utils.functional.noop(*args, **kwargs)
No operation.
Takes any arguments/keyword arguments and does nothing.
celery.utils.functional.first(predicate, it)
Return the first element in it that predicate accepts.
If predicate is None it will return the first item that’s not None.
celery.utils.functional.firstmethod(method, on_call=None)
Multiple dispatch.
Return a function that with a list of instances, finds the first instance that gives a value for the given method.
The list can also contain lazy instances (lazy.)
celery.utils.functional.chunks(it, n)
Split an iterator into chunks with n elements each.
Warning: it must be an actual iterator, if you pass this a concrete sequence will get you repeating elements.

So \texttt{chunks(iter(range(1000)), 10)} is fine, but \texttt{chunks(range(1000), 10)} is not.

Example

\begin{verbatim}
# n == 2 >>> x = chunks(iter([0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10]), 2) >>> list(x) [[0, 1], [2, 3], [4, 5], [6, 7], [8, 9], [10]]
# n == 3 >>> x = chunks(iter([0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10]), 3) >>> list(x) [[0, 1, 2], [3, 4, 5], [6, 7, 8], [9, 10]]
\end{verbatim}

celery.utils.functional.padlist (\texttt{container}, \texttt{size}, \texttt{default=None})

Pad list with default elements.

Example

\begin{verbatim}
>>> first, last, city = padlist(['George', 'Costanza', 'NYC'], 3)
('George', 'Costanza', 'NYC')
>>> first, last, city = padlist(['George', 'Costanza'], 3)
('George', 'Costanza', None)
>>> first, last, city, planet = padlist(...
...     ['George', 'Costanza', 'NYC'], 4, default='Earth',
... )
('George', 'Costanza', 'NYC', 'Earth')
\end{verbatim}

celery.utils.functional.mattrgetter (*\texttt{attrs})

Get attributes, ignoring attribute errors.

Like \texttt{operator.itemgetter()} but return \texttt{None} on missing attributes instead of raising \texttt{AttributeError}.

celery.utils.functional.uniq (\texttt{it})

Return all unique elements in \texttt{it}, preserving order.

celery.utils.functional.regen (\texttt{it})

Convert iterator to an object that can be consumed multiple times.

\texttt{Regen} takes any iterable, and if the object is an generator it will cache the evaluated list on first access, so that the generator can be “consumed” multiple times.

celery.utils.functional.dictfilter (\texttt{d=None}, **\texttt{kw})

Remove all keys from dict \texttt{d} whose value is \texttt{None}.

class celery.utils.functional.lazy (\texttt{fun}, *\texttt{args}, **\texttt{kwargs})

Holds lazy evaluation.

Evaluated when called or if the \texttt{evaluate()} method is called. The function is re-evaluated on every call.

\texttt{Overloaded operations that will evaluate the promise: \_\_str\_(), \_\_repr\_(), \_\_cmp\_().}

\texttt{evaluate()}

celery.utils.functional.maybe_evaluate (\texttt{value})

Evaluate value only if value is a \texttt{lazy} instance.

celery.utils.functional.head_from_fun (\texttt{fun}, \texttt{bound=False}, \texttt{debug=False})

Generate signature function from actual function.

celery.utils.functional.maybe (\texttt{typ}, \texttt{val})

Call \texttt{typ} on value if \texttt{val} is defined.
celery.utils.functional.fun_accepts_kwargs(fun)
Return true if function accepts arbitrary keyword arguments.

celery.utils.graph
Dependency graph implementation.

class celery.utils.graph.DOT
Constants related to the dot format.
ATTR = '{name}={value}'
ATTRSEP = ', '
DIRS = {'digraph': '->', 'graph': '--'}
EDGE = '{INp}"{0}" {dir} "{1}" [{attrs}]'
HEAD = '\n{IN}{type} {id} {{\n{INp}graph [{attrs}]\n'
NODE = '{INp}"{0}" [{attrs}]'
TAIL = '{IN})'}'

class celery.utils.graph.CycleError
A cycle was detected in an acyclic graph.

class celery.utils.graph.DependencyGraph(it=None, formatter=None)
A directed acyclic graph of objects and their dependencies.
Supports a robust topological sort to detect the order in which they must be handled.
Takes an optional iterator of (obj, dependencies) tuples to build the graph from.

Warning: Does not support cycle detection.

add_arc(obj)
Add an object to the graph.

add_edge(A, B)
Add an edge from object A to object B.
I.e. A depends on B.

connect(graph)
Add nodes from another graph.

edges()
Return generator that yields for all edges in the graph.

format(obj)

items()

iteritems()

repr_node(obj, level=1, fmt=('[0]([1])')

to_dot(fh, formatter=None)
Convert the graph to DOT format.

Parameters
  * fh (IO) – A file, or a file-like object to write the graph to.
Celery Documentation, Release 4.4.0

- **formatter** ([celery.utils.graph.GraphFormatter](#)) – Custom
  graph formatter to use.

  ```python
  toposort()
  Sort the graph topologically.
  Returns of objects in the order in which they must be handled.
  Return type List
  ```

  ```python
  update(it)
  Update graph with data from a list of (obj, deps) tuples.
  ```

  ```python
  valency_of(obj)
  Return the valency (degree) of a vertex in the graph.
  ```

  ```python
  class celery.utils.graph.GraphFormatter (root=None, type=None, id=None, indent=0, inw=' ', **scheme)
  Format dependency graphs.
  FMT(fmt, *args, **kwargs)
  attr(name, value)
  attrs(d, scheme=None)
  draw_edge(a, b, scheme=None, attrs=None)
  draw_node(obj, scheme=None, attrs=None)
  edge(a, b, **attrs)
  edge_scheme = {'arrowcolor': 'black', 'arrowsize': 0.7, 'color': 'darkseagreen4'}
  graph_scheme = {'bgcolor': 'mintcream'}
  head(**attrs)
  label(**attrs)
  node(obj, **attrs)
  node_scheme = {'color': 'palegreen4', 'fillcolor': 'palegreen3'}
  scheme = {'arrowhead': 'vee', 'fontname': 'HelveticaNeue', 'shape': 'box', 'style': 'filled'}
  tail()
  term_scheme = {'color': 'palegreen2', 'fillcolor': 'palegreen1'}
  terminal_node(obj, **attrs)

  **celery.utils.objects**

  Object related utilities, including introspection, etc.

  ```python
  class celery.utils.objects.Bunch(**kwargs)
  Object that enables you to modify attributes.
  ```

  ```python
  class celery.utils.objects.FallbackContext (provided, fallback, *fb_args, **fb_kwargs)
  Context workaround.
  The built-in @contextmanager utility does not work well when wrapping other contexts, as the traceback is
  wrong when the wrapped context raises.

  This solves this problem and can be used instead of @contextmanager in this example:

  ```
@contextmanager
def connection_or_default_connection(connection=None):
    if connection:
        # user already has a connection, shouldn't close
        # after use
        yield connection
    else:
        # must've new connection, and also close the connection
        # after the block returns
        with create_new_connection() as connection:
            yield connection

This wrapper can be used instead for the above like this:

def connection_or_default_connection(connection=None):
    return FallbackContext(connection, create_new_connection)

class celery.utils.objectsgetitem_property(keypath, doc=None)

Attribute -> dict key descriptor.
The target object must support __getitem__, and optionally __setitem__.

Example

```python
>>> from collections import defaultdict

>>> class Me(dict):
...     deep = defaultdict(dict)
...     ...
...     foo = _getitem_property('foo')
...     deep_thing = _getitem_property('deep.thing')

>>> me = Me()
>>> me.foo
None

>>> me.foo = 10
>>> me.foo
10
>>> me['foo']
10

>>> me.deep_thing = 42
>>> me.deep_thing
42
>>> me.deep
defaultdict(<type 'dict'>, {'thing': 42})
```

celery.utils.objects.mro_lookup(cls, attr=None, stop=None, monkey_patched=None)

Return the first node by MRO order that defines an attribute.

Parameters

- cls (Any) – Child class to traverse.
- attr (str) – Name of attribute to find.
- stop (Set[Any]) – A set of types that if reached will stop the search.
• **monkey_patched** *(Sequence)* – Use one of the stop classes if the attributes module origin isn’t in this list. Used to detect monkey patched attributes.

Returns The attribute value, or None if not found.

Return type Any

celery.utils.term

Terminals and colors.

```python
class celery.utils.term.colored(*s, **kwargs)
    Terminal colored text.

Example

```python
c = colored(enabled=True)
>>> print(str(c.red('the quick '), c.blue('brown ', c.bold('fox ')),
...       c.magenta(c.underline('jumps over')),
...       c.yellow(' the lazy '),
...       c.green('dog ')))
```

black (*s)
blink (*s)
blue (*s)
bold (*s)
bright (*s)
cyan (*s)
embed ()
green (*s)
ible (*s)
icyan (*s)
igreen (*s)
imagenta (*s)
ired (*s)
iwhite (*s)
iyellow (*s)
magenta (*s)
no_color ()
node (s, op)
red (*s)
reset (*s)
reverse (*s)
underline (*s)

3.12. Internals
Utilities related to dates, times, intervals, and timezones.

class celery.utils.time.LocalTimezone

    Local time implementation.

Note: Used only when the enable_utc setting is disabled.

dst(dt)
    datetime -> DST offset as timedelta positive east of UTC.

fromutc(dt)
    datetime in UTC -> datetime in local time.

tzname(dt)
    datetime -> string name of time zone.

utcoffset(dt)
    datetime -> timedelta showing offset from UTC, negative values indicating West of UTC

celery.utils.time.maybe_timedelta(delta)
    Convert integer to timedelta, if argument is an integer.

celery.utils.time.delta_resolution(dt, delta)
    Round a datetime to the resolution of timedelta.

    If the timedelta is in days, the datetime will be rounded to the nearest days, if the timedelta is in
    hours the datetime will be rounded to the nearest hour, and so on until seconds, which will just return the
    original datetime.

celery.utils.time.remaining(start, ends_in, now=None, relative=False)
    Calculate the remaining time for a start date and a timedelta.

    For example, “how many seconds left for 30 seconds after start?”

    Parameters
        • start (datetime) – Starting date.
        • ends_in (timedelta) – The end delta.
        • relative (bool) – If enabled the end time will be calculated using
delta_resolution() (i.e., rounded to the resolution of ends_in).
        • now (Callable) – Function returning the current time and date. Defaults to
datetime.utcnow().

    Returns Remaining time.

    Return type  timedelta

celery.utils.time.rate(r)
    Convert rate string ("100/m", "2/h" or "0.5/s") to seconds.

celery.utils.time.weekday(name)
    Return the position of a weekday: 0 - 7, where 0 is Sunday.
Example

```python
>>> weekday('sunday'), weekday('sun'), weekday('mon')
(0, 0, 1)
```

celery.utils.time.humanize_seconds(secs, prefix='', sep='', now='now', microseconds=False)
Show seconds in human form.

For example, 60 becomes “1 minute”, and 7200 becomes “2 hours”.

**Parameters**
- `prefix (str)` – can be used to add a preposition to the output (e.g., ‘in’ will give ‘in 1 second’, but add nothing to ‘now’).
- `now (str)` – Literal ‘now’.
- `microseconds (bool)` – Include microseconds.

celery.utils.time.maybe_iso8601(dt)
Either datetime | str -> datetime or None -> None.

celery.utils.time.is_naive(dt)
Return True if datetime is naive.

celery.utils.time.make_aware(dt, tz)
Set timezone for a datetime object.

celery.utils.time.localize(dt, tz)
Convert aware datetime to another timezone.

celery.utils.time.to_utc(dt)
Convert naive datetime to UTC.

celery.utils.time.maybe_make_aware(dt, tz=None)
Convert dt to aware datetime, do nothing if dt is already aware.

class celery.utils.time.ffwd(year=None, month=None, weeks=0, weekday=None, day=None, hour=None, minute=None, second=None, microsecond=None, **kwargs)
Version of dateutil.relativedelta that only supports addition.

celery.utils.time.utcoffset(time=<module 'time' (built-in)>, localtime=<built-in function localtime>)
Return the current offset to UTC in hours.

celery.utils.time.adjust_timestamp(ts, offset, here=<function utcoffset>)
Adjust timestamp based on provided utcoffset.

celery.utils.time.get_exponential_backoff_interval(factor, retries, maximum, full_jitter=False)
Calculate the exponential backoff wait time.

celery.utils.iso8601
Parse ISO8601 dates.

Originally taken from pyiso8601 (https://bitbucket.org/micktwomey/pyiso8601)

Modified to match the behavior of dateutil.parser:
- raise ValueError instead of ParseError
- return naive datetime by default
- uses pytz.FixedOffset

3.12. Internals

celery.utils.iso8601.parse_iso8601(datestring)

Parse and convert ISO-8601 string to datetime.

celery.utils.saferepr

Streaming, truncating, non-recursive version of `repr()`.

Differences from regular `repr()`:

- Sets are represented the Python 3 way: `{1, 2}` vs `set([1, 2])`.
- Unicode strings does not have the `u` prefix, even on Python 2.
- Empty set formatted as `set()` (Python 3), not `set([])` (Python 2).
- Longs don’t have the `L` suffix.

Very slow with no limits, super quick with limits.

celery.utils.saferepr.saferepr(o, maxlen=None, maxlevels=3, seen=None)

Safe version of `repr()`.

**Warning:** Make sure you set the maxlen argument, or it will be very slow for recursive objects. With the maxlen set, it’s often faster than built-in repr.

```python
celery.utils.saferepr.reprstream(stack, seen=None, maxlevels=3, level=0, isinstance=<built-in function isinstance>)
```

Streaming repr, yielding tokens.

**celery.utils.serialization**

Utilities for safely pickling exceptions.

```python
exception celery.utils.serialization.UnpickleableExceptionWrapper(exc_module,
exc_cls_name,
exc_args,
text=exc_args)
```

Wraps unpickleable exceptions.

**Parameters**
• \texttt{exc\_module} (str) – See \texttt{exc\_module}.
• \texttt{exc\_cls\_name} (str) – See \texttt{exc\_cls\_name}.
• \texttt{exc\_args} (Tuple[\textit{Any}, ...]) – See \texttt{exc\_args}.

\textbf{Example}

```python
>>> def pickle_it(raising_function):
...     try:
...         raising_function()
...     except Exception as e:
...         exc = UnpickleableExceptionWrapper(
...             e.__class__.__module__,
...             e.__class__.__name__,
...             e.args,
...         )
...     pickle.dumps(exc)  # Works fine.
```

\texttt{exc\_args} = None

The arguments for the original exception.

\texttt{exc\_cls\_name} = None

The name of the original exception class.

\texttt{exc\_module} = None

The module of the original exception.

\texttt{classmethod from\_exception}(exc)

\texttt{restore}()

celery.utils.serialization.subclass_exception(name, parent, module)

Create new exception class.

celery.utils.serialization.find\_pickleable\_exception(exc, loads=<built-in function loads>, dumps=<built-in function dumps>)

Find first pickleable exception base class.

With an exception instance, iterate over its super classes (by MRO) and find the first super exception that’s pickleable. It does not go below \texttt{Exception} (i.e., it skips \texttt{Exception}, \texttt{BaseException} and \texttt{object}). If that happens you should use \texttt{UnpickleableException} instead.

\textbf{Parameters}

• \texttt{exc} (BaseException) – An exception instance.
• \texttt{loads} – decoder to use.
• \texttt{dumps} – encoder to use

\textbf{Returns}

Nearest pickleable parent exception class (except \texttt{Exception} and parents), or if the exception is pickleable it will return None.

\textbf{Return type} Exception

celery.utils.serialization.create\_exception\_cls(name, module, parent=None)

Dynamically create an exception class.

celery.utils.serialization.get\_pickleable\_exception(exc)

Make sure exception is pickleable.

celery.utils.serialization.get\_pickleable\_etype(cls, loads=<built-in function loads>, dumps=<built-in function dumps>)

Get pickleable exception type.
celery.utils.serialization.get_pickled_exception(exc)
Reverse of get_pickleable_exception().

celery.utils.serialization.strtobool(term, table=None)
Convert common terms for true/false to bool.
Examples (true/false/yes/no/on/off/1/0).

celery.utils.sysinfo
System information utilities.
celery.utils.sysinfo.load_average()
Return system load average as a triple.

class celery.utils.sysinfo.df(path)
Disk information.
available
capacity
stat
total_blocks

celery.utils.threads
Threading primitives and utilities.
class celery.utils.threads.bgThread(name=None, **kwargs)
Background service thread.
body()
on_crash(msg, *fmt, **kwargs)
run()
Method representing the thread’s activity.
You may override this method in a subclass. The standard run() method invokes the callable object passed to the object’s constructor as the target argument, if any, with sequential and keyword arguments taken from the args and kwargs arguments, respectively.
stop()
Graceful shutdown.
class celery.utils.threads.Local
Local object.
celery.utils.threads.LocalStack
alias of celery.utils.threads._LocalStack
class celery.utils.threads.LocalManager (locals=None, ident_func=None)
Local objects cannot manage themselves.
For that you need a local manager. You can pass a local manager multiple locals or add them later by appending them to managerlocals. Every time the manager cleans up, it will clean up all the data left in the locals for this context.
The ident_func parameter can be added to override the default ident function for the wrapped locals.
**clearup()**
Manually clean up the data in the locals for this context.
Call this at the end of the request or use `make_middleware()`.

**get_ident()**
Return context identifier.
This is the identifier the local objects use internally for this context. You cannot override this method to change the behavior but use it to link other context local objects (such as SQLAlchemy’s scoped sessions) to the Werkzeug locals.

`celery.utils.threads.get_ident()` → integer
Return a non-zero integer that uniquely identifies the current thread amongst other threads that exist simultaneously. This may be used to identify per-thread resources. Even though on some platforms threads identities may appear to be allocated consecutive numbers starting at 1, this behavior should not be relied upon, and the number should be seen purely as a magic cookie. A thread’s identity may be reused for another thread after it exits.

`celery.utils.threads.default_socket_timeout(timeout)`
Context temporarily setting the default socket timeout.

**celery.utils.timer2**
Scheduler for Python functions.

**Note:** This is used for the thread-based worker only, not for amqp/redis/sqs/qpid where `kombu.asynchronous.timer` is used.

```python
class celery.utils.timer2.Entry (fun, args=None, kwargs=None)
    Schedule Entry.
    args
    cancel()
    canceled
    cancelled
    fun
    kwargs
    tref

celery.utils.timer2.Schedule
    alias of kombu.asynchronous.timer.Timer

class celery.utils.timer2.Timer (schedule=None, on_error=None, on_tick=None,
    on_start=None, max_interval=None, **kwars)
    Timer thread.
```

**Note:** This is only used for transports not supporting AsyncIO.

```python
class Entry (fun, args=None, kwargs=None)
    Schedule Entry.
    args
```

**3.12. Internals**
cancel()
canceled
cancelled
fun
kwargs
tref
Schedule
    alias of kombu.asynchronous.timer.Timer
call_after(*args, **kwargs)
call_at(*args, **kwargs)
call_repeatedly(*args, **kwargs)
cancel(tref)
clear()
empty()
ensure_started()
enter(entry, eta, priority=None)
enter_after(*args, **kwargs)
ext_after(secs, priority=10)
next()
on_tick = None
queue
run()
    Method representing the thread’s activity.
    You may override this method in a subclass. The standard run() method invokes the callable object passed
to the object’s constructor as the target argument, if any, with sequential and keyword arguments taken
from the args and kwargs arguments, respectively.

    running = False
stop()
celery.utils.timer2.to_timestamp(d, default_timezone=<UTC>, time=<built-in function monotonic>)
    Convert datetime to timestamp.
    If d’ is already a timestamp, then that will be used.

celery.utils.imports

Utilities related to importing modules and symbols by name.

exception celery.utils.imports.NotAPackage
    Raised when importing a package, but it’s not a package.
celery.utils.imports.qualname(obj)
    Return object name.
celery.utils.imports.

.. function:: instantiate(name, *args, **kwargs)

   Instantiate class by name.

   See also:

   symbol_by_name().

celery.utils.imports.

.. function:: symbol_by_name(name, aliases=None, imp=None, package=None, sep='.', default=None, **kwargs)

   Get symbol by qualified name.

   The name should be the full dot-separated path to the class:

   modulename.ClassName

   Example:

   

   .. code-block:: python

      celery.concurrency.processes.TaskPool

      ^-- class name

   or using ':' to separate module and symbol:

   celery.concurrency.processes:TaskPool

   If aliases is provided, a dict containing short name/long name mappings, the name is looked up in the aliases first.

   **Examples**

   

   .. code-block:: python

      >>> symbol_by_name('celery.concurrency.processes.TaskPool')
      <class 'celery.concurrency.processes.TaskPool'>

      >>> symbol_by_name('default', {
          ...         'default': 'celery.concurrency.processes.TaskPool'})
      <class 'celery.concurrency.processes.TaskPool'>

   # Does not try to look up non-string names. >>> from celery.concurrency.processes import TaskPool >>> symbol_by_name(TaskPool) is TaskPool True

celery.utils.imports.

.. function:: cwd_in_path()

   Context adding the current working directory to sys.path.

celery.utils.imports.

.. function:: find_module(module, path=None, imp=None)

   Version of imp.find_module() supporting dots.

celery.utils.imports.

.. function:: import_from_cwd(module, imp=None, package=None)

   Import module, temporarily including modules in the current directory.

   Modules located in the current directory has precedence over modules located in sys.path.

celery.utils.imports.

.. function:: reload_from_cwd(module, reloader=None)

   Reload module (ensuring that CWD is in sys.path).

celery.utils.imports.

.. function:: module_file(module)

   Return the correct original file name of a module.

celery.utils.imports.

.. function:: gen_task_name(app, name, module_name)

   Generate task name from name/module pair.
celery.utils.log

Logging utilities.

class celery.utils.log.ColorFormatter(fmt=None, use_color=True)
    
    Logging formatter that adds colors based on severity.

    
    Loglevel -> Color mapping.

    colors = {'CRITICAL': <bound method colored.magenta of ''>, 'DEBUG': <bound method colored.blue of ''>, 'ERROR': <bound method colored.red of ''>, 'WARNING': <bound method colored.yellow of ''}}

    format(record)
        
        Format the specified record as text.
        
        The record’s attribute dictionary is used as the operand to a string formatting operation which yields the returned string. Before formatting the dictionary, a couple of preparatory steps are carried out. The message attribute of the record is computed using LogRecord.getMessage(). If the formatting string uses the time (as determined by a call to usesTime(), formatTime() is called to format the event time. If there is exception information, it is formatted using formatException() and appended to the message.

    formatException(ei)
        
        Format and return the specified exception information as a string.
        
        This default implementation just uses traceback.print_exception()

class celery.utils.log.LoggingProxy(logger, loglevel=None)
    
    Forward file object to logging.Logger instance.

    Parameters
    * logger (Logger) – Logger instance to forward to.
    * loglevel (int, str) – Log level to use when logging messages.

close()

    closed = False

flush()

isatty()

    Here for file support.

loglevel = 40

mode = 'w'

name = None

write(data)

    Write message to logging object.

writelines(sequence)

    Write list of strings to file.
    
    The sequence can be any iterable object producing strings. This is equivalent to calling write() for each string.

celery.utils.log.set_in_sighandler(value)

    Set flag signifying that we’re inside a signal handler.

celery.utils.log.in_sighandler()

    Context that records that we are in a signal handler.

celery.utils.log.get_logger(name)

    Get logger by name.
celery.utils.log.get_task_logger(name)
Get logger for task module by name.

celery.utils.log.mlevel (level)
Convert level name/int to log level.

celery.utils.log.get_multiprocessing_logger()
Return the multiprocessing logger.

celery.utils.log.reset_multiprocessing_logger()
Reset multiprocessing logging setup.

celery.utils.text
Text formatting utilities.
celery.utils.text.abbr(S, max, ellipsis='...')
Abbreviate word.
celery.utils.text.abbrtask(S, max)
Abbreviate task name.
celery.utils.text.dedent(s, n=4, sep='n')
Remove indentation.
celery.utils.text.dedent_initial(s, n=4)
Remove indentation from first line of text.
celery.utils.text.ensure_newlines(s, n=2)
Ensure text s ends in separator sep'.
celery.utils.text.ensure_sep(sep, s, n=2)
Ensure text s ends in separator sep'.
celery.utils.text.fill_paragraphs(s, width, sep='n')
Fill paragraphs with newlines (or custom separator).
celery.utils.text.indent(t, indent=0, sep='n')
Indent text.
celery.utils.text.join(l, sep='n')
Concatenate list of strings.
celery.utils.text.pluralize(n, text, suffix='s')
Pluralize term when n is greater than one.
celery.utils.text.pretty(value, width=80, nl_width=80, sep='n', **kw)
Format value for printing to console.
celery.utils.text.str_to_list(s)
Convert string to list.
celery.utils.text.simple_format(s, keys, pattern=re.compile('%(\w)'), expand='\1')
Format string, expanding abbreviations in keys'.
celery.utils.text.truncate(s, maxlen=128, suffix='...')
Truncate text to a maximum number of characters.

celery.utils.dispatch
Observer pattern.

3.12. Internals
class celery.utils.dispatch.Signal(providing_args=None, use_caching=False, name=None)
Create new signal.

Keyword Arguments
- **providing_args** (List) – A list of the arguments this signal can pass along in a send() call.
- **use_caching** (bool) – Enable receiver cache.
- **name** (str) – Name of signal, used for debugging purposes.

connect(*args, **kwargs)
Connect receiver to sender for signal.

Parameters
- **receiver** (Callable) – A function or an instance method which is to receive signals. Receivers must be hashable objects.
  
    if weak is True, then receiver must be weak-referenceable.

Receivers must be able to accept keyword arguments.
If receivers have a dispatch_uid attribute, the receiver will not be added if another receiver already exists with that dispatch_uid.
- **sender** (Any) – The sender to which the receiver should respond. Must either be a Python object, or None to receive events from any sender.
- **weak** (bool) – Whether to use weak references to the receiver. By default, the module will attempt to use weak references to the receiver objects. If this parameter is false, then strong references will be used.
- **dispatch_uid** (Hashable) – An identifier used to uniquely identify a particular instance of a receiver. This will usually be a string, though it may be anything hashable.
- **retry** (bool) – If the signal receiver raises an exception (e.g. ConnectionError), the receiver will be retried until it runs successfully. A strong ref to the receiver will be stored and the weak option will be ignored.

disconnect(receiver=None, sender=None, weak=None, dispatch_uid=None)
Disconnect receiver from sender for signal.

If weak references are used, disconnect needn’t be called. The receiver will be removed from dispatch automatically.

Parameters
- **receiver** (Callable) – The registered receiver to disconnect. May be none if dispatch_uid is specified.
- **sender** (Any) – The registered sender to disconnect.
- **weak** (bool) – The weakref state to disconnect.
- **dispatch_uid** (Hashable) – The unique identifier of the receiver to disconnect.

has_listeners(sender=None)

receivers = None
Holds a dictionary of {receiverkey (id): weakref(receiver)} mappings.

send(sender, **named)
Send signal from sender to all connected receivers.

If any receiver raises an error, the error propagates back through send, terminating the dispatch loop, so it is quite possible to not have all receivers called if a raises an error.

Parameters
- **sender** (Any) – The sender of the signal. Either a specific object or None.
- ****named (Any) – Named arguments which will be passed to receivers.

Returns of tuple pairs: [(receiver, response), ...].
Return type  List

send_robust (sender, **named)
Send signal from sender to all connected receivers.
If any receiver raises an error, the error propagates back through send, terminating the dispatch loop, so it is quite possible to not have all receivers called if a raises an error.

Parameters
- **sender (Any)** – The sender of the signal. Either a specific object or None.
- **named (Any)** – Named arguments which will be passed to receivers.

Returns  of tuple pairs: [(receiver, response), … ].
Return type  List

celery.utils.dispatch.signal
Implementation of the Observer pattern.

class celery.utils.dispatch.signal.Signal (providing_args=None, use_caching=False, name=None)
Create new signal.

Keyword Arguments
- **providing_args (List)** – A list of the arguments this signal can pass along in a send() call.
- **use_caching (bool)** – Enable receiver cache.
- **name (str)** – Name of signal, used for debugging purposes.

connect (*args, **kwargs)
Connect receiver to sender for signal.

Parameters
- **receiver (Callable)** – A function or an instance method which is to receive signals. Receivers must be hashable objects.

  if weak is True, then receiver must be weak-referenceable.

  Receivers must be able to accept keyword arguments.

  If receivers have a dispatch_uid attribute, the receiver will not be added if another receiver already exists with that dispatch_uid.
- **sender (Any)** – The sender to which the receiver should respond. Must either be a Python object, or None to receive events from any sender.
- **weak (bool)** – Whether to use weak references to the receiver. By default, the module will attempt to use weak references to the receiver objects. If this parameter is false, then strong references will be used.
- **dispatch_uid (Hashable)** – An identifier used to uniquely identify a particular instance of a receiver. This will usually be a string, though it may be anything hashable.
- **retry (bool)** – If the signal receiver raises an exception (e.g. ConnectionError), the receiver will be retried until it runs successfully. A strong ref to the receiver will be stored and the weak option will be ignored.

disconnect (receiver=None, sender=None, weak=None, dispatch_uid=None)
Disconnect receiver from sender for signal.

If weak references are used, disconnect needn’t be called. The receiver will be removed from dispatch automatically.

Parameters
- **receiver (Callable)** – The registered receiver to disconnect. May be none if dispatch_uid is specified.
Celery Documentation, Release 4.4.0

- **sender** (*Any*) – The registered sender to disconnect.
- **weak** (*bool*) – The weakref state to disconnect.
- **dispatch_uid** (*Hashable*) – The unique identifier of the receiver to disconnect.

```python
has_listeners (sender=None)
```

```python
receivers = None
```

Holds a dictionary of `{receiverkey (id): weakref(receiver)}` mappings.

```python
send (sender, **named)
```

Send signal from sender to all connected receivers.

If any receiver raises an error, the error propagates back through send, terminating the dispatch loop, so it is quite possible to not have all receivers called if a raises an error.

**Parameters**
- **sender** (*Any*) – The sender of the signal. Either a specific object or `None`.
- **named** (*Any*) – Named arguments which will be passed to receivers.

**Returns** of tuple pairs: `[(receiver, response), ...]`.

**Return type** `List`

```python
send_robust (sender, **named)
```

Send signal from sender to all connected receivers.

If any receiver raises an error, the error propagates back through send, terminating the dispatch loop, so it is quite possible to not have all receivers called if a raises an error.

**Parameters**
- **sender** (*Any*) – The sender of the signal. Either a specific object or `None`.
- **named** (*Any*) – Named arguments which will be passed to receivers.

**Returns** of tuple pairs: `[(receiver, response), ...]`.

**Return type** `List`

**celery.utils.dispatch.weakref_backports**

Weakref compatibility.

weakref_backports is a partial backport of the weakref module for Python versions below 3.4.

Copyright (C) 2013 Python Software Foundation, see LICENSE.python for details.

The following changes were made to the original sources during backporting:
- Added `self` to `super` calls.
- Removed `from None` when raising exceptions.

```python
class celery.utils.dispatch.weakref_backports.WeakMethod
```

Weak reference to bound method.

A custom `weakref.ref` subclass which simulates a weak reference to a bound method, working around the lifetime problem of bound methods.

**celery.platforms**

Platforms.

Utilities dealing with platform specifics: signals, daemonization, users, groups, and so on.

```python
celery.platforms.pyimplementation()
```

Return string identifying the current Python implementation.
exception celery.platforms.LockFailed
    Raised if a PID lock can’t be acquired.

celery.platforms.get_fdmax (default=None)
    Return the maximum number of open file descriptors on this system.
    Keyword Arguments default – Value returned if there’s no file descriptor limit.

class celery.platforms.Pidfile(path)
    Pidfile.

    This is the type returned by create_pidlock().

    See also:

    Best practice is to not use this directly but rather use the create_pidlock() function instead: more convenient and also removes stale pidfiles (when the process holding the lock is no longer running).

    acquire()
        Acquire lock.

    is_locked()
        Return true if the pid lock exists.

    path = None
        Path to the pid lock file.

    read_pid()
        Read and return the current pid.

    release(*args)
        Release lock.

    remove()
        Remove the lock.

    remove_if_stale()
        Remove the lock if the process isn’t running.
        I.e. process does not respons to signal.

    write_pid()

celery.platforms.create_pidlock(pidfile)
    Create and verify pidfile.

    If the pidfile already exists the program exits with an error message, however if the process it refers to isn’t running anymore, the pidfile is deleted and the program continues.

    This function will automatically install an atexit handler to release the lock at exit, you can skip this by calling _create_pidlock() instead.

    Returns used to manage the lock.

    Return type Pidfile

Example

```python
>>> pidlock = create_pidlock('/var/run/app.pid')
```

celery.platforms.close_open_fds(keep=None)
class celery.platforms.DaemonContext (pidfile=None, workdir=None, umask=None, fake=False, after_chdir=None, after_forkers=True, **kwargs)

Context manager daemonizing the process.

close(*args)
open()
redirect_to_null(fd)

celery.platforms.detached (logfile=None, pidfile=None, uid=None, gid=None, umask=0, workdir=None, fake=False, **opts)

Detach the current process in the background (daemonize).

Parameters

- **logfile**(str) – Optional log file. The ability to write to this file will be verified before the process is detached.
- **pidfile**(str) – Optional pid file. The pidfile won’t be created, as this is the responsibility of the child. But the process will exit if the pid lock exists and the pid written is still running.
- **uid**(int, str) – Optional user id or user name to change effective privileges to.
- **gid**(int, str) – Optional group id or group name to change effective privileges to.
- **umask**(str, int) – Optional umask that’ll be effective in the child process.
- **workdir**(str) – Optional new working directory.
- **fake**(bool) – Don’t actually detach, intended for debugging purposes.
- ****opts**(Any) – Ignored.

Example

```python
>>> from celery.platforms import detached, create_pidlock
>>> with detached(  
...     logfile='/var/log/app.log',  
...     pidfile='/var/run/app.pid',  
...     uid='nobody'):  
...     # Now in detached child process with effective user set to nobody,  
...     # and we know that our logfile can be written to, and that  
...     # the pidfile isn't locked.  
...     pidlock = create_pidlock('/var/run/app.pid')  
...     # Run the program  
...     program.run(logfile='/var/log/app.log')
```

celery.platforms.parse_uid (uid)

Parse user id.

Parameters **uid**(str, int) – Actual uid, or the username of a user.

Returns The actual uid.

Return type int

celery.platforms.parse_gid (gid)

Parse group id.

Parameters **gid**(str, int) – Actual gid, or the name of a group.

Returns The actual gid of the group.

Return type int

celery.platforms.setgroups (groups)

Set active groups from a list of group ids.
celery.platforms.initgroups \( (uid, \text{gid}) \)
Init process group permissions.

Compat version of \texttt{os.initgroups()} that was first added to Python 2.7.

celery.platforms.setgid \( (\text{gid}) \)
Version of \texttt{os.setgid()} supporting group names.

celery.platforms.setuid \( (\text{uid}) \)
Version of \texttt{os.setuid()} supporting usernames.

celery.platforms.maybe_drop_privileges \( (uid=None, \text{gid}=None) \)
Change process privileges to new user/group.

If UID and GID is specified, the real user/group is changed.

If only UID is specified, the real user is changed, and the group is changed to the users primary group.

If only GID is specified, only the group is changed.

celery.platforms.signal_name \( (\text{signum}) \)
Return name of signal from signal number.

celery.platforms.set_process_title \( (\text{proname}, \text{info}=None) \)
Set the \texttt{ps} name for the currently running process.

Only works if \texttt{setproctitle} is installed.

celery.platforms.set_mp_process_title \( (\text{proname}, \text{info}=None, \text{hostname}=None) \)
Set the \texttt{ps} name from the current process name.

Only works if \texttt{setproctitle} is installed.

celery.platforms.get_errno_name \( (n) \)
Get errno for string (e.g., ENOENT).

celery.platforms.ignore_errno \( (*\text{errnos}, **\text{kwargs}) \)
Context manager to ignore specific POSIX error codes.

Takes a list of error codes to ignore: this can be either the name of the code, or the code integer itself:

```python
>>> with ignore_errno('ENOENT'):
...     with open('foo', 'r') as fh:
...         return fh.read()
```

```python
>>> with ignore_errno(errno.ENOENT, errno.EPERM):
...     pass
```

\textbf{Parameters types} \( (\text{Tuple}[\text{Exception}]) \) – A tuple of exceptions to ignore (when the errno matches). Defaults to \texttt{Exception}.

celery.platforms.fd_by_path \( (\text{paths}) \)
Return a list of file descriptors.

This method returns list of file descriptors corresponding to file paths passed in \texttt{paths} variable.

\textbf{Parameters paths} – List[\text{str}]: List of file paths.
\textbf{Returns} List of file descriptors.
\textbf{Return type} List[int]
Example

```python
>>> keep = fd_by_path(['/dev/urandom', '/my/precious/'])
```

celery.platforms.isatty(fh)
Return true if the process has a controlling terminal.

celery._state
Internal state.

This is an internal module containing thread state like the current_app, and current_task.

This module shouldn’t be used directly.

celery._state.set_default_app(app)
Set default app.

celery._state.get_current_app()

celery._state.get_current_task()
Currently executing task.

celery._state.get_current_worker_task()
Currently executing task, that was applied by the worker.

This is used to differentiate between the actual task executed by the worker and any task that was called within a task (using task.__call__ or task.apply)

celery._state.current_app = <Celery default>
Proxy to current app.

celery._state.current_task = None
Proxy to current task.

celery._state.connect_on_app_finalize(callback)
Connect callback to be called when any app is finalized.

Release 4.4
Date Dec 16, 2019

3.13.1 What’s new in Celery 4.2 (windowlicker)

Author Omer Katz(omer.drow at gmail.com)
Celery is a simple, flexible, and reliable distributed system to process vast amounts of messages, while providing operations with the tools required to maintain such a system.

It’s a task queue with focus on real-time processing, while also supporting task scheduling.

Celery has a large and diverse community of users and contributors, you should come join us on IRC or our mailing-list.

To read more about Celery you should go read the introduction.

While this version is backward compatible with previous versions it’s important that you read the following section. This version is officially supported on CPython 2.7, 3.4, 3.5 & 3.6 and is also supported on PyPy.

**Table of Contents**

Make sure you read the important notes before upgrading to this version.

- Preface
  - Wall of Contributors
- Important Notes
  - Supported Python Versions
- News
  - Result Backends
  - Canvas
  - Tasks
  - Sphinx Extension

**Preface**

The 4.2.0 release continues to improve our efforts to provide you with the best task execution platform for Python.

This release is mainly a bug fix release, ironing out some issues and regressions found in Celery 4.0.0.

Traditionally, releases were named after Autechre’s track names. This release continues this tradition in a slightly different way. Each major version of Celery will use a different artist’s track names as codenames.

From now on, the 4.x series will be codenamed after Aphex Twin’s track names. This release is codenamed after his very famous track, Windowlicker.

Thank you for your support!

— Omer Katz

Note: This wall was automatically generated from git history, so sadly it doesn’t not include the people who help with more important things like answering mailing-list questions.

Important Notes

Supported Python Versions

The supported Python Versions are:

- CPython 2.7
News

Result Backends

New Redis Sentinel Results Backend

Redis Sentinel provides high availability for Redis. A new result backend supporting it was added.

Cassandra Results Backend

A new `cassandra_options` configuration option was introduced in order to configure the cassandra client. See *Cassandra backend settings* for more information.

DynamoDB Results Backend

A new `dynamodb_endpoint_url` configuration option was introduced in order to point the result backend to a local endpoint during development or testing. See *AWS DynamoDB backend settings* for more information.

Python 2/3 Compatibility Fixes

Both the CouchDB and the Consul result backends accepted byte strings without decoding them to Unicode first. This is now no longer the case.

Canvas

Multiple bugs were resolved resulting in a much smoother experience when using Canvas.

Tasks

Bound Tasks as Error Callbacks

We fixed a regression that occurred when bound tasks are used as error callbacks. This used to work in Celery 3.x but raised an exception in 4.x until this release.

In both 4.0 and 4.1 the following code wouldn’t work:
```python
@app.task(name="raise_exception", bind=True)
def raise_exception(self):
    raise Exception("Bad things happened")

@app.task(name="handle_task_exception", bind=True)
def handle_task_exception(self):
    print("Exception detected")

subtask = raise_exception.subtask()
subtask.apply_async(link_error=handle_task_exception.s())
```

### Task Representation

- Shadowing task names now works as expected. The shadowed name is properly presented in flower, the logs and the traces.
- `argsrepr` and `kwargsrepr` were previously not used even if specified. They now work as expected. See [Hiding sensitive information in arguments](#) for more information.

### Custom Requests

We now allow tasks to use custom `request` classes for custom task classes. See [Requests and custom requests](#) for more information.

### Retries with Exponential Backoff

Retries can now be performed with exponential backoffs to avoid overwhelming external services with requests. See [Automatic retry for known exceptions](#) for more information.

### Sphinx Extension

Tasks were supposed to be automatically documented when using Sphinx’s Autodoc was used. The code that would have allowed automatic documentation had a few bugs which are now fixed.

Also, The extension is now documented properly. See [Documenting Tasks with Sphinx](#) for more information.

### 3.13.2 Change history

This document contains change notes for bugfix releases in the 4.x series, please see [What’s new in Celery 4.2 (windowlicker)](#) for an overview of what’s new in Celery 4.2.

#### 4.2.1

- **release-date** 2018-07-18 11:00 AM IST
- **release-by** Omer Katz
• **Result Backend**: Fix deserialization of exceptions that are present in the producer codebase but not in the consumer codebase.
  Contributed by John Arnold

• **Message Protocol Compatibility**: Fix error caused by an invalid (None) timelimit value in the message headers when migrating messages from 3.x to 4.x.
  Contributed by Robert Kopaczewski

• **Result Backend**: Fix serialization of exception arguments when exception arguments are not JSON serializable by default.
  Contributed by Tom Booth

• **Worker**: Fixed multiple issues with rate limited tasks
  Maintain scheduling order. Fix possible scheduling of a celery.worker.request.Request with the wrong kombu.utils.limits.TokenBucket which could cause tasks’ rate limit to behave incorrectly.
  Fix possible duplicated execution of tasks that were rate limited or if ETA/Countdown was provided for them.
  Contributed by @ideascf

• **Worker**: Defensively handle invalid timelimit header values in requests.
  Contributed by Omer Katz

Documentation fixes:

• Matt Wiens
• Seunghun Lee
• Lewis M. Kabui
• Prathamesh Salunkhe

### 4.2.0

**release-date** 2018-06-10 21:30 PM IST
**release-by** Omer Katz

• **Task**: Add `ignore_result` as task execution option (#4709, #3834)
  Contributed by Andrii Kostenko and George Psarakis.

• **Redis Result Backend**: Do not create PubSub subscriptions when results are ignored (#4709, #3834)
  Contributed by Andrii Kostenko and George Psarakis.

• **Redis Result Backend**: Result consumer always unsubscribes when task state is ready (#4666)
  Contributed by George Psarakis.

• **Development/Testing**: Add docker-compose and base Dockerfile for development (#4482)
  Contributed by Chris Mitchell.

• **Documentation/Sphinx**: Teach autodoc to document tasks if undoc-members is not set (#4588)
  Contributed by Leo Singer.

• **Documentation/Sphinx**: Put back undoc-members option in sphinx test (#4586)
  Contributed by Leo Singer.

• **Documentation/Sphinx**: Sphinx autodoc picks up tasks automatically only if `undoc-members` is set (#4584)
Contributed by **Leo Singer**.

- **Task**: Fix shadow_name issue when using previous version Task class (#4572)
  Contributed by @pachewise.

- **Task**: Add support for bound tasks as `link_error` parameter (Fixes #3723) (#4545)
  Contributed by @brabiega.

- **Deployment**: Add a command line option for setting the Result Backend URL (#4549)
  Contributed by @y0ngdi.

- **CI**: Enable pip cache in appveyor build (#4546)
  Contributed by Thijs Triemstra.

- **Concurrency/Asynpool**: Fix errno property name shadowing.
  Contributed by Omer Katz.

- **DynamoDB Backend**: Configurable endpoint URL (#4532)
  Contributed by Bohdan Rybak.

- **Timezones**: Correctly detect UTC timezone and timezone from settings (Fixes #4517) (#4519)
  Contributed by @last-partizan.

- **Control**: Cleanup the mailbox’s producer pool after forking (#4472)
  Contributed by Nick Eaket.

- **Documentation**: Start Celery and Celery Beat on Azure WebJob (#4484)
  Contributed by PauloPeres.

- **Celery Beat**: Schedule due tasks on startup, after Beat restart has occurred (#4493)
  Contributed by Igor Kasianov.

- **Worker**: Use absolute time when task is accepted by worker pool (#3684)
  Contributed by Régis Behmo.

- **Canvas**: Propagate arguments to chains inside groups (#4481)
  Contributed by Chris Mitchell.

- **Canvas**: Fix `Task.replace` behavior in nested chords (fixes #4368) (#4369)
  Contributed by Denis Shirokov & Alex Hill.

- **Installation**: Pass python_requires argument to setuptools (#4479)
  Contributed by Jon Dufresne.

- **Message Protocol Compatibility**: Handle “hybrid” messages that have moved between Celery versions (#4358) (Issue #4356)
  Contributed by Russell Keith-Magee.

- **Canvas**: request on_timeout now ignores soft time limit exception (fixes #4412) (#4473)
  Contributed by Alex Garel.

- **Redis Result Backend**: Integration test to verify PubSub unsubscriptions (#4468)
  Contributed by George Psarakis.
- **Message Protocol Properties**: Allow the shadow keyword argument and the shadow_name method to set shadow properly (#4381)
  
  Contributed by @hclihn.

- **Canvas**: Run chord_unlock on same queue as chord body (#4448) (Issue #4337)
  
  Contributed by Alex Hill.

- **Canvas**: Support chords with empty header group (#4443)
  
  Contributed by Alex Hill.

- **Timezones**: make astimezone call in localize more safe (#4324)
  
  Contributed by Matt Davis.

- **Canvas**: Fix length-1 and nested chords (#4437) (Issues #4393, #4055, #3885, #3597, #3574, #3323, #4301)
  
  Contributed by Alex Hill.

- **CI**: Run Openstack Bandit in Travis CI in order to detect security issues.
  
  Contributed by Omer Katz.

- **CI**: Run isort in Travis CI in order to lint Python import statements.
  
  Contributed by Omer Katz.

- **Canvas**: Resolve TypeError on .get from nested groups (#4432) (Issue #4274)
  
  Contributed by Misha Wolfson.

- **CouchDB Backend**: Correct CouchDB key string type for Python 2/3 compatibility (#4166)
  
  Contributed by @fmind & Omer Katz.

- **Group Result**: Fix current_app fallback in GroupResult.restore() (#4431)
  
  Contributed by Alex Hill.

- **Consul Backend**: Correct key string type for Python 2/3 compatibility (#4416)
  
  Contributed by Wido den Hollander.

- **Group Result**: Correctly restore an empty GroupResult (#2202) (#4427)
  
  Contributed by Alex Hill & Omer Katz.

- **Result**: Disable synchronous waiting for sub-tasks on eager mode (#4322)
  
  Contributed by Denis Podlesniy.

- **Celery Beat**: Detect timezone or Daylight Saving Time changes (#1604) (#4403)
  
  Contributed by Vincent Barbaresi.

- **Canvas**: Fix append to an empty chain. Fixes #4047. (#4402)
  
  Contributed by Omer Katz.

- **Task**: Allow shadow to override task name in trace and logging messages. (#4379)
  
  Contributed by @hclihn.

- **Documentation/Sphinx**: Fix getfullargspec Python 2.x compatibility in contrib/sphinx.py (#4399)
  
  Contributed by Javier Martin Montull.

- **Documentation**: Updated installation instructions for SQS broker (#4382)
Contributed by Sergio Fernandez.

- **Celery Beat**: Better equality comparison for ScheduleEntry instances (#4312)
  Contributed by @mariia-zelenova.

- **Task**: Adding ‘shadow’ property to as_task_v2 (#4350)
  Contributed by Marcelo Da Cruz Pinto.

- Try to import directly, do not use deprecated imp method (#4216)
  Contributed by Tobias Kunze.

- **Task**: Enable `kwargsrepr` and `argsrepr` override for modifying task argument representation (#4260)
  Contributed by James M. Allen.

- **Result Backend**: Add Redis Sentinel backend (#4144)
  Contributed by Geoffrey Bauduin.

- Use unique time values for Collections/LimitedSet (#3879 and #3891) (#3892)
  Contributed by @lead2gold.

- **CI**: Report coverage for all result backends.
  Contributed by Omer Katz.

- **Django**: Use Django DB max age connection setting (fixes #4116) (#4292)
  Contributed by Marco Schweighauser.

- **Canvas**: Properly take into account chain tasks link_error (#4240)
  Contributed by @agladkov.

- **Canvas**: Allow to create group with single task (fixes issue #4255) (#4280)
  Contributed by @agladkov.

- **Canvas**: Copy dictionary parameter in chord.from_dict before modifying (fixes issue #4223) (#4278)
  Contributed by @agladkov.

- **Results Backend**: Add Cassandra options (#4224)
  Contributed by Scott Cooper.

- **Worker**: Apply rate limiting for tasks with ETA (#4251)
  Contributed by @arpanshah29.

- **Celery Beat**: support scheduler entries without a schedule (#4235)
  Contributed by Markus Kaiserswerth.

- **SQS Broker**: Updated SQS requirements file with correct boto3 version (#4231)
  Contributed by Alejandro Varas.

- Remove unused code from _create_app contextmanager (#4204)
  Contributed by Ryan P Kilby.

- **Group Result**: Modify GroupResult.as_tuple() to include parent (fixes #4106) (#4205)
  Contributed by @pachewise.

- **Beat**: Set default scheduler class in beat command. (#4189)
Contributed by @Kxrr.

- **Worker**: Retry signal receiver after raised exception (#4192)
  
  Contributed by David Davis.

- **Task**: Allow custom Request class for tasks (#3977)
  
  Contributed by Manuel Vázquez Acosta.

- **Django**: Django fixup should close all cache backends (#4187)
  
  Contributed by Raphaël Riel.

- **Deployment**: Adds stopasgroup to the supervisor scripts (#4200)
  
  Contributed by @martialp.

- Using Exception.args to serialize/deserialize exceptions (#4085)
  
  Contributed by Alexander Ovechkin.

- **Timezones**: Correct calculation of application current time with timezone (#4173)
  
  Contributed by George Psarakis.

- **Remote Debugger**: Set the SO_REUSEADDR option on the socket (#3969)
  
  Contributed by Theodore Dubois.

- **Django**: Celery ignores exceptions raised during django.setup() (#4146)
  
  Contributed by Kevin Gu.

- Use heartbeat setting from application configuration for Broker connection (#4148)
  
  Contributed by @mperice.

- **Celery Beat**: Fixed exception caused by next_transit receiving an unexpected argument. (#4103)
  
  Contributed by DDevine.

- **Task** Introduce exponential backoff with Task auto-retry (#4101)
  
  Contributed by David Baumgold.

- **AsyncResult**: Remove weak-references to bound methods inAsyncResult promises. (#4131)
  
  Contributed by Vinod Chandru.

- **Development/Testing**: Allow eager application of canvas structures (#4576)
  
  Contributed by Nicholas Pilon.

- **Command Line**: Flush stderr before exiting with error code 1.
  
  Contributed by Antonin Delpeuch.

- **Task**: Escapes single quotes in kwargsrepr strings.
  
  Contributed by Kareem Zidane

- **AsyncResult**: Restore ability to join over ResultSet after fixing celery/#3818.
  
  Contributed by Derek Harland

- **Redis Results Backend**: Unsubscribe on message success.
  
  Previously Celery would leak channels, filling the memory of the Redis instance.
  
  Contributed by George Psarakis
• **Task**: Only convert eta to isoformat when it is not already a string.
  Contributed by **Omer Katz**

• **Redis Results Backend**: The result_backend setting now supports rediss:// URIs
  Contributed by **James Remeika**

• **Canvas** Keyword arguments are passed to tasks in chain as expected.
  Contributed by @tothegump

• **Django** Fix a regression causing Celery to crash when using Django.
  Contributed by **Jonas Haag**

• **Canvas** Chain with one task now runs as expected.
  Contributed by @tothegump

• **Kombu** Celery 4.2 now requires Kombu 4.2 or better.
  Contributed by **Omer Katz & Asif Saifuddin Auvi**

• **GreenletExit** is not in __all__ in greenlet.py which can not be imported by Python 3.6.
  The import was adjusted to work on Python 3.6 as well.
  Contributed by **Hsiaoming Yang**

• Fixed a regression that occurred during the development of Celery 4.2 which caused celery report to crash when Django is installed.
  Contributed by **Josue Balandrano Coronel**

• Matched the behavior of GroupResult.as_tuple() to that ofAsyncResult.as_tuple().
  The group’s parent is now serialized correctly.
  Contributed by **Josue Balandrano Coronel**

• Use Redis coercion mechanism for converting URI query parameters.
  Contributed by **Justin Patrin**

• Fixed the representation of GroupResult.
  The dependency graph is now presented correctly.
  Contributed by **Josue Balandrano Coronel**

Documentation, CI, Installation and Tests fixes:

• **Sammie S. Taunton**
• **Dan Wilson**
• **@pachewise**
• **Sergi Almacellas Abellana**
• **Omer Katz**
• **Alex Zaitsev**
• **Leo Singer**
• **Rachel Johnson**
• **Jon Dufresne**

**3.13. History**
3.13.3 What’s new in Celery 4.1 (latentcall)

Author Omer Katz (omer.drow at gmail.com)

Change history

What’s new documents describe the changes in major versions, we also have a Change history that lists the changes in bugfix releases (0.0.x), while older series are archived under the History section.
Celery is a simple, flexible, and reliable distributed system to process vast amounts of messages, while providing operations with the tools required to maintain such a system.

It’s a task queue with focus on real-time processing, while also supporting task scheduling.

Celery has a large and diverse community of users and contributors, you should come join us on IRC or our mailing-list.

To read more about Celery you should go read the introduction.

While this version is backward compatible with previous versions it’s important that you read the following section. This version is officially supported on CPython 2.7, 3.4, 3.5 & 3.6 and is also supported on PyPy.

**Table of Contents**

Make sure you read the important notes before upgrading to this version.

  - Wall of Contributors
- Important Notes
  - Added support for Python 3.6 & PyPy 5.8.0
- News
  - Result Backends
  - Periodic Tasks
  - Tasks
  - Canvas

**Preface**

The 4.1.0 release continues to improve our efforts to provide you with the best task execution platform for Python.

This release is mainly a bug fix release, ironing out some issues and regressions found in Celery 4.0.0.

We added official support for Python 3.6 and PyPy 5.8.0.

This is the first time we release without Ask Solem as an active contributor. We’d like to thank him for his hard work in creating and maintaining Celery over the years.

Since Ask Solem was not involved there were a few kinks in the release process which we promise to resolve in the next release. This document was missing when we did release Celery 4.1.0. Also, we did not update the release codename as we should have. We apologize for the inconvenience.

For the time being, I, Omer Katz will be the release manager.

Thank you for your support!

Note: This wall was automatically generated from git history, so sadly it doesn’t include the people who help with more important things like answering mailing-list questions.

Important Notes
Added support for Python 3.6 & PyPy 5.8.0

We now run our unit test suite and integration test suite on Python 3.6.x and PyPy 5.8.0.

We expect newer versions of PyPy to work but unfortunately we do not have the resources to test PyPy with those versions.

The supported Python Versions are:

- CPython 2.7
- CPython 3.4
- CPython 3.5
- CPython 3.6
- PyPy 5.8 (`pypy2`)

News

Result Backends

New DynamoDB Results Backend

We added a new results backend for those of you who are using DynamoDB.

If you are interested in using this results backend, refer to *AWS DynamoDB backend settings* for more information.

Elasticsearch

The Elasticsearch results backend is now more robust and configurable.

See *Elasticsearch backend settings* for more information about the new configuration options.

Redis

The Redis results backend can now use TLS to encrypt the communication with the Redis database server.

See *Redis backend settings*.

MongoDB

The MongoDB results backend can now handle binary-encoded task results.

This was a regression from 4.0.0 which resulted in a problem using serializers such as MsgPack or Pickle in conjunction with the MongoDB results backend.

Periodic Tasks

The task schedule now updates automatically when new tasks are added. Now if you use the Django database scheduler, you can add and remove tasks from the schedule without restarting Celery beat.
Tasks

The `disable_sync_subtasks` argument was added to allow users to override disabling synchronous subtasks. See *Avoid launching synchronous subtasks*

Canvas

Multiple bugs were resolved resulting in a much smoother experience when using Canvas.

3.13.4 Change history

4.1.1

- **release-date**: 2018-05-21 12:48 PM PST
- **release-by**: Omer Katz

**Important**: Please upgrade as soon as possible or pin Kombu to 4.1.0.

- **Breaking Change**: The module `async` in Kombu changed to `asynchronous`.
  Contributed by Omer Katz & Asif Saifuddin Auvi

4.1.0

- **release-date**: 2017-07-25 00:00 PM PST
- **release-by**: Omer Katz

- **Configuration**: `CELERY_SEND_EVENTS` instead of `CELERYD_SEND_EVENTS` for 3.1.x compatibility (#3997)
  Contributed by abhinav nilaratna.
- **App**: Restore behavior so Broadcast queues work. (#3934)
  Contributed by Patrick Cloke.
- **Sphinx**: Make appstr use standard format (#4134) (#4139)
  Contributed by Preston Moore.
- **App**: Make id, name always accessible from logging.Formatter via extra (#3994)
  Contributed by Yoichi NAKAYAMA.
- **Worker**: Add `worker_shutting_down` signal (#3998)
  Contributed by Daniel Huang.
- **PyPy**: Support PyPy version 5.8.0 (#4128)
  Contributed by Omer Katz.
- **Results**: Elasticsearch: Fix serializing keys (#3924)
  Contributed by @staticfox.
• **Canvas**: Deserialize all tasks in a chain (#4015)
  Contributed by @fcoelho.
• **Systemd**: Recover loglevel for ExecStart in systemd config (#4023)
  Contributed by Yoichi NAKAYAMA.
• **Sphinx**: Use the Sphinx add_directive_to_domain API (#4037)
  Contributed by Patrick Cloke.
• **App**: Pass properties to before_task_publish signal (#4035)
  Contributed by Javier Domingo Cansino.
• **Results**: Add SSL option for Redis backends (#3831)
  Contributed by Chris Kuehl.
• **Beat**: celery.schedule.crontab: fix reduce (#3826) (#3827)
  Contributed by Taylor C. Richberger.
• **State**: Fix celery issues when using flower REST API
  Contributed by Thierry RAMORASOAVINA.
• **Results**: Elasticsearch: Fix serializing document id.
  Contributed by Acey9.
• **Beat**: Make shallow copy of schedules dictionary
  Contributed by Brian May.
• **Beat**: Populate heap when periodic tasks are changed
  Contributed by Wojciech Zywno.
• **Task**: Allow class methods to define tasks (#3952)
  Contributed by georgepsarakis.
• **Platforms**: Always return boolean value when checking if signal is supported (#3962).
  Contributed by Jian Yu.
• **Canvas**: Avoid duplicating chains in chords (#3779)
  Contributed by Ryan Hiebert.
• **Canvas**: Lookup task only if list has items (#3847)
  Contributed by Marc Gibbons.
• **Results**: Allow unicode message for exception raised in task (#3903)
  Contributed by George Psarakis.
• **Python3**: Support for Python 3.6 (#3904, #3903, #3736)
  Contributed by Jon Dufresne, George Psarakis, Asif Saifuddin Auvi, Omer Katz.
• **App**: Fix retried tasks with expirations (#3790)
  Contributed by Brendan MacDonell.
  • Fix items format route in docs (#3875)
  Contributed by Slam.
• **Utils**: Fix `maybe_make_aware` (#3850)
  Contributed by Taylor C. Richberger.

• **Task**: Fix task ETA issues when timezone is defined in configuration (#3867)
  Contributed by George Psarakis.

• **Concurrency**: Consumer does not shutdown properly when embedded in gevent application (#3746)
  Contributed by Arcadiy Ivanov.

• **Canvas**: Fix #3725: Task replaced with group does not complete (#3731)
  Contributed by Morgan Doocy.

• **Task**: Correct order in chains with replaced tasks (#3730)
  Contributed by Morgan Doocy.

• **Result**: Enable synchronous execution of sub-tasks (#3696)
  Contributed by shalev67.

• **Task**: Fix request context for blocking task apply (added hostname) (#3716)
  Contributed by Marat Sharafutdinov.

• **Utils**: Fix task argument handling (#3678) (#3693)
  Contributed by Roman Sichny.

• **Beat**: Provide a transparent method to update the Scheduler heap (#3721)
  Contributed by Alejandro Pernin.

• **Beat**: Specify default value for pidfile option of celery beat. (#3722)
  Contributed by Arnaud Rocher.

• **Results**: Elasticsearch: Stop generating a new field every time when a new result is being put (#3708)
  Contributed by Mike Chen.

• **Requirements**
  – Now depends on Kombu 4.1.0.

• **Results**: Elasticsearch now reuses fields when new results are added.
  Contributed by Mike Chen.

• **Results**: Fixed MongoDB integration when using binary encodings (Issue #3575).
  Contributed by Andrew de Quincey.

• **Worker**: Making missing `*args` and `**kwargs` in Task protocol 1 return empty value in protocol 2 (Issue #3687).
  Contributed by Roman Sichny.

• **App**: Fixed `TypeError` in AMQP when using deprecated signal (Issue #3707).
  Contributed by @michael-k.

• **Beat**: Added a transparent method to update the scheduler heap.
  Contributed by Alejandro Pernin.

• **Task**: Fixed handling of tasks with keyword arguments on Python 3 (Issue #3657).
Contributed by **Roman Sichny**.

- **Task**: Fixed request context for blocking task apply by adding missing hostname attribute.
  Contributed by **Marat Sharafutdinov**.

- **Task**: Added option to run subtasks synchronously with `disable_sync_subtasks` argument.
  Contributed by **@shalev67**.

- **App**: Fixed chaining of replaced tasks (Issue #3726).
  Contributed by **Morgan Doocy**.

- **Canvas**: Fixed bug where replaced tasks with groups were not completing (Issue #3725).
  Contributed by **Morgan Doocy**.

- **Worker**: Fixed problem where consumer does not shutdown properly when embedded in a gevent application (Issue #3745).
  Contributed by **Arcadiy Ivanov**.

- **Results**: Added support for using AWS DynamoDB as a result backend (#3736).
  Contributed by **George Psarakis**.

- **Testing**: Added caching on pip installs.
  Contributed by **@orf**.

- **Worker**: Prevent consuming queue before ready on startup (Issue #3620).
  Contributed by **Alan Hamlett**.

- **App**: Fixed task ETA issues when timezone is defined in configuration (Issue #3753).
  Contributed by **George Psarakis**.

- **Utils**: `maybe_make_aware` should not modify datetime when it is already timezone-aware (Issue #3849).
  Contributed by **Taylor C. Richberger**.

- **App**: Fixed retrying tasks with expirations (Issue #3734).
  Contributed by **Brendan MacDonell**.

- **Results**: Allow unicode message for exceptions raised in task (Issue #3858).
  Contributed by **@staticfox**.

- **Canvas**: Fixed `IndexError` raised when chord has an empty header.
  Contributed by **Marc Gibbons**.

- **Canvas**: Avoid duplicating chains in chords (Issue #3771).
  Contributed by **Ryan Hiebert** and **George Psarakis**.

- **Utils**: Allow class methods to define tasks (Issue #3863).
  Contributed by **George Psarakis**.

- **Beat**: Populate heap when periodic tasks are changed.
  Contributed by **@wzywno** and **Brian May**.

- **Results**: Added support for Elasticsearch backend options settings.
  Contributed by **@Acey9**.
• **Events**: Ensure `Task.as_dict()` works when not all information about task is available.
  Contributed by @tramora.

• **Schedules**: Fixed pickled crontab schedules to restore properly (Issue #3826).
  Contributed by Taylor C. Richberger.

• **Results**: Added SSL option for redis backends (Issue #3830).
  Contributed by Chris Kuehl.

Celery is a simple, flexible, and reliable distributed system to process vast amounts of messages, while providing operations with the tools required to maintain such a system.

It’s a task queue with focus on real-time processing, while also supporting task scheduling.

Celery has a large and diverse community of users and contributors, you should come join us on IRC or our mailing-list.

To read more about Celery you should go read the introduction.

While this version is backward compatible with previous versions it’s important that you read the following section.

This version is officially supported on CPython 2.7, 3.4, and 3.5. and also supported on PyPy.
Celery Documentation, Release 4.4.0

• Preface
  – Wall of Contributors
• Upgrading from Celery 3.1
  – Step 1: Upgrade to Celery 3.1.25
  – Step 2: Update your configuration with the new setting names
  – Step 3: Read the important notes in this document
  – Step 4: Upgrade to Celery 4.0
• Important Notes
  – Dropped support for Python 2.6
  – Last major version to support Python 2
  – Django support
  – Removed features
    * Features removed for simplicity
    * Features removed for lack of funding
  – New Task Message Protocol
  – Lowercase setting names
  – Json is now the default serializer
  – The Task base class no longer automatically register tasks
  – Task argument checking
  – Redis Events not backward compatible
  – Redis Priorities Reversed
  – Django: Auto-discover now supports Django app configurations
  – Worker direct queues no longer use auto-delete
  – Old command-line programs removed
• News
  – New protocol highlights
  – Prefork Pool Improvements
    * Tasks now log from the child process
    * Ofair is now the default scheduling strategy
    * Limit child process resident memory size
    * One log-file per child process
  – Transports
    * RabbitMQ priority queue support
    * Configure broker URL for read/write separately
    * RabbitMQ queue extensions support
• Amazon SQS transport now officially supported
• Apache QPid transport now officially supported

– Redis: Support for Sentinel

– Tasks
  • Task Auto-retry Decorator
  • Task.replace Improvements
  • Remote Task Tracebacks
  • Handling task connection errors
  • Gevent/Eventlet: Dedicated thread for consuming results
  • AsyncResult.then(on_success, on_error)
  • New Task Router API
  • Canvas Refactor

– Periodic Tasks
  • New API for configuring periodic tasks
  • Optimized Beat implementation
  • Schedule tasks based on sunrise, sunset, dawn and dusk

– Result Backends
  • RPC Result Backend matured
  • Redis: Result backend optimizations
  • New Riak result backend introduced
  • New CouchDB result backend introduced
  • New Consul result backend introduced
  • Brand new Cassandra result backend
  • New Elasticsearch result backend introduced
  • New File-system result backend introduced

– Event Batching

– In Other News…
  • Requirements
  • Tasks
  • Beat
  • App
  • Logging
  • Execution Pools

– Testing
  • Transports
Welcome to Celery 4!

This is a massive release with over two years of changes. Not only does it come with many new features, but it also fixes a massive list of bugs, so in many ways you could call it our “Snow Leopard” release.

The next major version of Celery will support Python 3.5 only, where we are planning to take advantage of the new asyncio library.

This release would not have been possible without the support of my employer, Robinhood (we’re hiring!).

• Ask Solem

Dedicated to Sebastian “Zeb” Bjørnerud (RIP), with special thanks to Ty Wilkins, for designing our new logo, all the contributors who help make this happen, and my colleagues at Robinhood.

Note: This wall was automatically generated from git history, so sadly it doesn’t not include the people who help with more important things like answering mailing-list questions.

Upgrading from Celery 3.1

Step 1: Upgrade to Celery 3.1.25

If you haven’t already, the first step is to upgrade to Celery 3.1.25.

This version adds forward compatibility to the new message protocol, so that you can incrementally upgrade from 3.1 to 4.0.

Deploy the workers first by upgrading to 3.1.25, this means these workers can process messages sent by clients using both 3.1 and 4.0.

After the workers are upgraded you can upgrade the clients (e.g. web servers).
Step 2: Update your configuration with the new setting names

This version radically changes the configuration setting names, to be more consistent.
The changes are fully backwards compatible, so you have the option to wait until the old setting names are deprecated, but to ease the transition we have included a command-line utility that rewrites your settings automatically.
See Lowercase setting names for more information.

Step 3: Read the important notes in this document

Make sure you are not affected by any of the important upgrade notes mentioned in the following section.
An especially important note is that Celery now checks the arguments you send to a task by matching it to the signature (Task argument checking).

Step 4: Upgrade to Celery 4.0

At this point you can upgrade your workers and clients with the new version.

Important Notes

Dropped support for Python 2.6

Celery now requires Python 2.7 or later, and also drops support for Python 3.3 so supported versions are:
- CPython 2.7
- CPython 3.4
- CPython 3.5
- PyPy 5.4 (pypy2)
- PyPy 5.5-alpha (pypy3)

Last major version to support Python 2

Starting from Celery 5.0 only Python 3.5+ will be supported.
To make sure you’re not affected by this change you should pin the Celery version in your requirements file, either to a specific version: celery==4.0.0, or a range: celery>=4.0,<5.0.
Dropping support for Python 2 will enable us to remove massive amounts of compatibility code, and going with Python 3.5 allows us to take advantage of typing, async/await, asyncio, and similar concepts there’s no alternative for in older versions.
Celery 4.x will continue to work on Python 2.7, 3.4, 3.5; just as Celery 3.x still works on Python 2.6.

Django support

Celery 4.x requires Django 1.8 or later, but we really recommend using at least Django 1.9 for the new transaction.on_commit feature.
A common problem when calling tasks from Django is when the task is related to a model change, and you wish to cancel the task if the transaction is rolled back, or ensure the task is only executed after the changes have been written to the database.

`transaction.atomic` enables you to solve this problem by adding the task as a callback to be called only when the transaction is committed.

Example usage:

```python
from functools import partial
from django.db import transaction

from .models import Article, Log
from .tasks import send_article_created_notification

def create_article(request):
    with transaction.atomic():
        article = Article.objects.create(**request.POST)
        # send this task only if the rest of the transaction succeeds.
        transaction.on_commit(partial(
            send_article_created_notification.delay, article_id=article.pk)
        )
        Log.objects.create(type=Log.ARTICLE_CREATED, object_pk=article.pk)
```

**Removed features**

- Microsoft Windows is no longer supported.
  The test suite is passing, and Celery seems to be working with Windows, but we make no guarantees as we are unable to diagnose issues on this platform. If you are a company requiring support on this platform, please get in touch.
- Jython is no longer supported.

**Features removed for simplicity**

- Webhook task machinery (`celery.task.http`) has been removed.
  Nowadays it’s easy to use the `requests` module to write webhook tasks manually. We would love to use requests but we are simply unable to as there’s a very vocal ‘anti-dependency’ mob in the Python community
  If you need backwards compatibility you can simply copy + paste the 3.1 version of the module and make sure it’s imported by the worker: https://github.com/celery/celery/blob/3.1/celery/task/http.py

- Tasks no longer sends error emails.
  This also removes support for `app.mail_admins`, and any functionality related to sending emails.

- `celery.contrib.batches` has been removed.
  This was an experimental feature, so not covered by our deprecation timeline guarantee.
  You can copy and paste the existing batches code for use within your projects: https://github.com/celery/celery/blob/3.1/celery/contrib/batches.py
Features removed for lack of funding

We announced with the 3.1 release that some transports were moved to experimental status, and that there’d be no official support for the transports.

As this subtle hint for the need of funding failed we’ve removed them completely, breaking backwards compatibility.

- Using the Django ORM as a broker is no longer supported.
  You can still use the Django ORM as a result backend: see `django-celery-results - Using the Django ORM/Cache as a result backend` section for more information.

- Using SQLAlchemy as a broker is no longer supported.
  You can still use SQLAlchemy as a result backend.

- Using CouchDB as a broker is no longer supported.
  You can still use CouchDB as a result backend.

- Using IronMQ as a broker is no longer supported.

- Using Beanstalk as a broker is no longer supported.

In addition some features have been removed completely so that attempting to use them will raise an exception:

- The `--autoreload` feature has been removed.
  This was an experimental feature, and not covered by our deprecation timeline guarantee. The flag is removed completely so the worker will crash at startup when present. Luckily this flag isn’t used in production systems.

- The experimental `threads` pool is no longer supported and has been removed.

- The `force_execv` feature is no longer supported.
  The `celery worker` command now ignores the `--no-execv, --force-execv, and the CELERYD_FORCE_EXECV` setting.
  This flag will be removed completely in 5.0 and the worker will raise an error.

- The old legacy “amqp” result backend has been deprecated, and will be removed in Celery 5.0.
  Please use the `rpc` result backend for RPC-style calls, and a persistent result backend for multi-consumer results.

We think most of these can be fixed without considerable effort, so if you’re interested in getting any of these features back, please get in touch.

Now to the good news…

New Task Message Protocol

This version introduces a brand new task message protocol, the first major change to the protocol since the beginning of the project.

The new protocol is enabled by default in this version and since the new version isn’t backwards compatible you have to be careful when upgrading.

The 3.1.25 version was released to add compatibility with the new protocol so the easiest way to upgrade is to upgrade to that version first, then upgrade to 4.0 in a second deployment.

If you wish to keep using the old protocol you may also configure the protocol version number used:
app = Celery()
app.conf.task_protocol = 1

Read more about the features available in the new protocol in the news section found later in this document.

**Lowercase setting names**

In the pursuit of beauty all settings are now renamed to be in all lowercase and some setting names have been renamed for consistency.

This change is fully backwards compatible so you can still use the uppercase setting names, but we would like you to upgrade as soon as possible and you can do this automatically using the `celery upgrade settings` command:

```
$ celery upgrade settings proj/settings.py
```

This command will modify your module in-place to use the new lower-case names (if you want uppercase with a “CELERY” prefix see block below), and save a backup in `proj/settings.py.orig`.

**For Django users and others who want to keep uppercase names**

If you’re loading Celery configuration from the Django settings module then you’ll want to keep using the uppercase names.

You also want to use a `CELERY_` prefix so that no Celery settings collide with Django settings used by other apps.

To do this, you’ll first need to convert your settings file to use the new consistent naming scheme, and add the prefix to all Celery related settings:

```
$ celery upgrade settings proj/settings.py --django
```

After upgrading the settings file, you need to set the prefix explicitly in your `proj/celery.py` module:

```
app.config_from_object('django.conf:settings', namespace='CELERY')
```

You can find the most up to date Django Celery integration example here: *First steps with Django.*

**Note:** This will also add a prefix to settings that didn’t previously have one, for example `BROKER_URL` should be written `CELERY_BROKER_URL` with a namespace of `CELERYCELERY_BROKER_URL`.

Luckily you don’t have to manually change the files, as the `celery upgrade settings --django` program should do the right thing.

The loader will try to detect if your configuration is using the new format, and act accordingly, but this also means you’re not allowed to mix and match new and old setting names, that’s unless you provide a value for both alternatives.

The major difference between previous versions, apart from the lowercase names, are the renaming of some prefixes, like `celerybeat_` to `beat_`, `celeryd_` to `worker_`.

The `celery_` prefix has also been removed, and task related settings from this name-space is now prefixed by `task_`. worker related settings with `worker_`.

Apart from this most of the settings will be the same in lowercase, apart from a few special ones:

</table>

You can see a full table of the changes in New lowercase settings.

**Json is now the default serializer**

The time has finally come to end the reign of pickle as the default serialization mechanism, and json is the default serializer starting from this version.

This change was announced with the release of Celery 3.1.

If you’re still depending on pickle being the default serializer, then you have to configure your app before upgrading to 4.0:

```python
task_serializer = 'pickle'
result_serializer = 'pickle'
accept_content = ('pickle')
```

The Json serializer now also supports some additional types:

- datetime, time, date
• **Decimal**
  Converted to json text.

• **django.utils.functional.Promise**
  Django only: Lazy strings used for translation etc., are evaluated and conversion to a json type is attempted.

• **uuid.UUID**
  Converted to json text.

You can also define a __json__ method on your custom classes to support JSON serialization (must return a json compatible type):

```python
class Person:
    first_name = None
    last_name = None
    address = None

    def __json__(self):
        return {
            'first_name': self.first_name,
            'last_name': self.last_name,
            'address': self.address,
        }
```

### The Task base class no longer automatically register tasks

The `Task` class is no longer using a special meta-class that automatically registers the task in the task registry. Instead this is now handled by the `app.task` decorators.

If you’re still using class based tasks, then you need to register these manually:

```python
class CustomTask(Task):
    def run(self):
        print('running')
CustomTask = app.register_task(CustomTask())
```

The best practice is to use custom task classes only for overriding general behavior, and then using the task decorator to realize the task:

```python
@app.task(bind=True, base=CustomTask)
def custom(self):
    print('running')
```

This change also means that the `abstract` attribute of the task no longer has any effect.

### Task argument checking

The arguments of the task are now verified when calling the task, even asynchronously:
>>> @app.task
... def add(x, y):
...     return x + y

>>> add.delay(8, 8)
<AsyncResult: f59d71ca-1549-43e0-be41-4e8821a83c0c>

>>> add.delay(8)
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
  File "celery/app/task.py", line 376, in delay
    return self.apply_async(args, kwargs)
  File "celery/app/task.py", line 485, in apply_async
    check_arguments(*(args or ()), **(kwargs or {}))
TypeError: add() takes exactly 2 arguments (1 given)

You can disable the argument checking for any task by setting its `typing` attribute to `False`:

>>> @app.task(typing=False)
... def add(x, y):
...     return x + y

Or if you would like to disable this completely for all tasks you can pass `strict_typing=False` when creating the app:

```python
app = Celery(..., strict_typing=False)
```

**Redis Events not backward compatible**

The Redis `fanout_patterns` and `fanout_prefix` transport options are now enabled by default.

Workers/monitors without these flags enabled won’t be able to see workers with this flag disabled. They can still execute tasks, but they cannot receive each others monitoring messages.

You can upgrade in a backward compatible manner by first configuring your 3.1 workers and monitors to enable the settings, before the final upgrade to 4.0:

```python
BROKER_TRANSPORT_OPTIONS = {
    'fanout_patterns': True,
    'fanout_prefix': True,
}
```

**Redis Priorities Reversed**

Priority 0 is now lowest, 9 is highest.

This change was made to make priority support consistent with how it works in AMQP.

Contributed by Alex Koshelev.

**Django: Auto-discover now supports Django app configurations**

The `autodiscover_tasks()` function can now be called without arguments, and the Django handler will automatically find your installed apps:
app.autodiscover_tasks()

The Django integration example in the documentation has been updated to use the argument-less call.
This also ensures compatibility with the new, ehm, AppConfig stuff introduced in recent Django versions.

Worker direct queues no longer use auto-delete

Workers/clients running 4.0 will no longer be able to send worker direct messages to workers running older versions, and vice versa.
If you’re relying on worker direct messages you should upgrade your 3.x workers and clients to use the new routing settings first, by replacing celery.utils.worker_direct() with this implementation:

```python
from kombu import Exchange, Queue

worker_direct_exchange = Exchange('C.dq2')

def worker_direct(hostname):
    return Queue(
        '{hostname}.dq2'.format(hostname),
        exchange=worker_direct_exchange,
        routing_key=hostname,
    )
```

This feature closed Issue #2492.

Old command-line programs removed

Installing Celery will no longer install the celeryd, celerybeat and celeryd-multi programs.
This was announced with the release of Celery 3.1, but you may still have scripts pointing to the old names, so make sure you update these to use the new umbrella command:

<table>
<thead>
<tr>
<th>Program</th>
<th>New Status</th>
<th>Replacement</th>
</tr>
</thead>
<tbody>
<tr>
<td>celeryd</td>
<td>REMOVED</td>
<td>celery worker</td>
</tr>
<tr>
<td>celerybeat</td>
<td>REMOVED</td>
<td>celery beat</td>
</tr>
<tr>
<td>celeryd-multi</td>
<td>REMOVED</td>
<td>celery multi</td>
</tr>
</tbody>
</table>

News

New protocol highlights

The new protocol fixes many problems with the old one, and enables some long-requested features:
- Most of the data are now sent as message headers, instead of being serialized with the message body.
  In version 1 of the protocol the worker always had to deserialize the message to be able to read task meta-data like the task id, name, etc. This also meant that the worker was forced to double-decode the data, first deserializing the message on receipt, serializing the message again to send to child process, then finally the child process deserializes the message again.
Keeping the meta-data fields in the message headers means the worker doesn’t actually have to decode the payload before delivering the task to the child process, and also that it’s now possible for the worker to reroute a task written in a language different from Python to a different worker.

- A new `lang` message header can be used to specify the programming language the task is written in.
- Worker stores results for internal errors like `ContentDisallowed`, and other deserialization errors.
- Worker stores results and sends monitoring events for unregistered task errors.
- Worker calls callbacks/errbacks even when the result is sent by the parent process (e.g., `WorkerLostError` when a child process terminates, deserialization errors, unregistered tasks).
- A new `origin` header contains information about the process sending the task (worker node-name, or PID and host-name information).
- A new `shadow` header allows you to modify the task name used in logs.

This is useful for dispatch like patterns, like a task that calls any function using pickle (don’t do this at home):

```python
from celery import Task
from celery.utils.imports import qualname

class call_as_task(Task):
    def shadow_name(self, args, kwargs, options):
        return 'call_as_task:{0}'.format(qualname(args[0]))
    def run(self, fun, *args, **kwargs):
        return fun(*args, **kwargs)
call_as_task = app.register_task(call_as_task())
```

- New `argsrepr` and `kwargsrepr` fields contain textual representations of the task arguments (possibly truncated) for use in logs, monitors, etc.

This means the worker doesn’t have to deserialize the message payload to display the task arguments for informational purposes.

- Chains now use a dedicated `chain` field enabling support for chains of thousands and more tasks.
- New `parent_id` and `root_id` headers adds information about a tasks relationship with other tasks.
  - `parent_id` is the task id of the task that called this task
  - `root_id` is the first task in the work-flow.

  These fields can be used to improve monitors like flower to group related messages together (like chains, groups, chords, complete work-flows, etc).

- `app.TaskProducer` replaced by `app.amqp.create_task_message()` and `app.amqp.send_task_message()`.

Dividing the responsibilities into creating and sending means that people who want to send messages using a Python AMQP client directly, don’t have to implement the protocol.

The `app.amqp.create_task_message()` method calls either `app.amqp.as_task_v2()`, or `app.amqp.as_task_v1()` depending on the configured task protocol, and returns a special `task_message` tuple containing the headers, properties and body of the task message.

See also:
The new task protocol is documented in full here: Version 2.
Prefork Pool Improvements

Tasks now log from the child process

Logging of task success/failure now happens from the child process executing the task. As a result logging utilities, like Sentry can get full information about tasks, including variables in the traceback stack.

--Ofair is now the default scheduling strategy

To re-enable the default behavior in 3.1 use the -Ofast command-line option.

There’s been lots of confusion about what the -Ofair command-line option does, and using the term “prefetch” in explanations have probably not helped given how confusing this terminology is in AMQP.

When a Celery worker using the prefork pool receives a task, it needs to delegate that task to a child process for execution.

The prefork pool has a configurable number of child processes (--concurrency) that can be used to execute tasks, and each child process uses pipes/sockets to communicate with the parent process:

- inqueue (pipe/socket): parent sends task to the child process
- outqueue (pipe/socket): child sends result/return value to the parent.

In Celery 3.1 the default scheduling mechanism was simply to send the task to the first inqueue that was writable, with some heuristics to make sure we round-robin between them to ensure each child process would receive the same amount of tasks.

This means that in the default scheduling strategy, a worker may send tasks to the same child process that is already executing a task. If that task is long running, it may block the waiting task for a long time. Even worse, hundreds of short-running tasks may be stuck behind a long running task even when there are child processes free to do work.

The -Ofair scheduling strategy was added to avoid this situation, and when enabled it adds the rule that no task should be sent to the a child process that is already executing a task.

The fair scheduling strategy may perform slightly worse if you have only short running tasks.

Limit child process resident memory size

You can now limit the maximum amount of memory allocated per prefork pool child process by setting the worker --max-memory-per-child option, or the worker_max_memory_per_child setting.

The limit is for RSS/resident memory size and is specified in kilobytes.

A child process having exceeded the limit will be terminated and replaced with a new process after the currently executing task returns.

See Max memory per child setting for more information.

Contributed by Dave Smith.

One log-file per child process

Init-scrips and celery multi now uses the %I log file format option (e.g., /var/log/celery/%n%I.log).

This change was necessary to ensure each child process has a separate log file after moving task logging to the child process, as multiple processes writing to the same log file can cause corruption.
You’re encouraged to upgrade your init-scripts and `celery multi` arguments to use this new option.

## Transports

### RabbitMQ priority queue support

See *RabbitMQ Message Priorities* for more information.

Contributed by Gerald Manipon.

### Configure broker URL for read/write separately

New `broker_read_url` and `broker_write_url` settings have been added so that separate broker URLs can be provided for connections used for consuming/publishing.

In addition to the configuration options, two new methods have been added the app API:

- `app.connection_for_read()`
- `app.connection_for_write()`

These should now be used in place of `app.connection()` to specify the intent of the required connection.

**Note:** Two connection pools are available: `app.pool` (read), and `app.producer_pool` (write). The latter doesn’t actually give connections but full `kombu.Producer` instances.

```python
def publish_some_message(app, producer=None):
    with app.producer_or_acquire(producer) as producer:
        ...

def consume_messages(app, connection=None):
    with app.connection_or_acquire(connection) as connection:
        ...
```

### RabbitMQ queue extensions support

Queue declarations can now set a message TTL and queue expiry time directly, by using the `message_ttl` and `expires` arguments

New arguments have been added to `Queue` that lets you directly and conveniently configure RabbitMQ queue extensions in queue declarations:

- `Queue(expires=20.0)`
  
  Set queue expiry time in float seconds.

  See `kombu.Queue.expires`.

- `Queue(message_ttl=30.0)`
  
  Set queue message time-to-live float seconds.

  See `kombu.Queue.message_ttl`.

- `Queue(max_length=1000)`
Set queue max length (number of messages) as int.

See `kombu.Queue.max_length`.

- `Queue(max_length_bytes=1000)`

  Set queue max length (message size total in bytes) as int.

  See `kombu.Queue.max_length_bytes`.

- `Queue(max_priority=10)`

  Declare queue to be a priority queue that routes messages based on the priority field of the message.

  See `kombu.Queue.max_priority`.

### Amazon SQS transport now officially supported

The SQS broker transport has been rewritten to use async I/O and as such joins RabbitMQ, Redis and QPid as officially supported transports.

The new implementation also takes advantage of long polling, and closes several issues related to using SQS as a broker.

This work was sponsored by Nextdoor.

### Apache QPid transport now officially supported

Contributed by Brian Bouterse.

### Redis: Support for Sentinel

You can point the connection to a list of sentinel URLs like:

```
sentinel://0.0.0.0:26379;sentinel://0.0.0.0:26380/...
```

where each sentinel is separated by a ;. Multiple sentinels are handled by `kombu.Connection constructor`, and placed in the alternative list of servers to connect to in case of connection failure.

Contributed by Sergey Azovskov, and Lorenzo Mancini.

### Tasks

#### Task Auto-retry Decorator

Writing custom retry handling for exception events is so common that we now have built-in support for it.

For this a new `autoretry_for` argument is now supported by the task decorators, where you can specify a tuple of exceptions to automatically retry for:

```python
from twitter.exceptions import FailWhaleError

@app.task(autoretry_for=(FailWhaleError,))
def refresh_timeline(user):
    return twitter.refresh_timeline(user)
```
See *Automatic retry for known exceptions* for more information.

Contributed by Dmitry Malinovsky.

**Task.replace Improvements**

- `self.replace(signature)` can now replace any task, chord or group, and the signature to replace with can be a chord, group or any other type of signature.

- No longer inherits the callbacks and errbacks of the existing task.
  
  If you replace a node in a tree, then you wouldn’t expect the new node to inherit the children of the old node.

- `Task.replace_in_chord` has been removed, use `.replace` instead.

- If the replacement is a group, that group will be automatically converted to a chord, where the callback “accumulates” the results of the group tasks.

  A new built-in task (*celery.accumulate* was added for this purpose)

Contributed by Steeve Morin, and Ask Solem.

**Remote Task Tracebacks**

The new `task_remote_tracebacks` will make task tracebacks more useful by injecting the stack of the remote worker.

This feature requires the additional tblib library.

Contributed by Ionel Cristian Mărășeșt.

**Handling task connection errors**

Connection related errors occurring while sending a task is now re-raised as a `kombu.exceptions.OperationalError` error:

```
>>> try:
...   add.delay(2, 2)
... except add.OperationalError as exc:
...   print('Could not send task %r: %r' % (add, exc))
```

See *Connection Error Handling* for more information.

**Gevent/Eventlet: Dedicated thread for consuming results**

When using gevent, or eventlet there is now a single thread responsible for consuming events.

This means that if you have many calls retrieving results, there will be a dedicated thread for consuming them:

```
result = add.delay(2, 2)

# this call will delegate to the result consumer thread:
# once the consumer thread has received the result this greenlet can
# continue.
value = result.get(timeout=3)
```
This makes performing RPC calls when using gevent/eventlet perform much better.

**AsyncResult.then(on_success, on_error)**

TheAsyncResult API has been extended to support the promise protocol. This currently only works with the RPC (amqp) and Redis result backends, but lets you attach callbacks to when tasks finish:

```python
import gevent.monkey
monkey.patch_all()

import time
from celery import Celery

app = Celery(broker='amqp://', backend='rpc')

@app.task
def add(x, y):
    return x + y

def on_result_ready(result):
    print('Received result for id %r: %r' % (result.id, result.result,))

add.delay(2, 2).then(on_result_ready)

time.sleep(3)  # run gevent event loop for a while.
```

Demonstrated using gevent here, but really this is an API that’s more useful in callback-based event loops like twisted, or tornado.

**New Task Router API**

The `task_routes` setting can now hold functions, and map routes now support glob patterns and regexes. Instead of using router classes you can now simply define a function:

```python
def route_for_task(name, args, kwargs, options, task=None, **kwargs):
    from proj import tasks
    
    if name == tasks.add.name:
        return {'queue': 'hipri'}
```

If you don’t need the arguments you can use start arguments, just make sure you always also accept star arguments so that we have the ability to add more features in the future:

```python
def route_for_task(name, *args, **kwargs):
    from proj import tasks
    if name == tasks.add.name:
        return {'queue': 'hipri', 'priority': 9}
```

Both the `options` argument and the new `task` keyword argument are new to the function-style routers, and will make it easier to write routers based on execution options, or properties of the task.

The optional `task` keyword argument won’t be set if a task is called by name using `app.send_task()`.

For more examples, including using glob/regexes in routers please see `task_routes` and Automatic routing.
Canvas Refactor

The canvas/work-flow implementation have been heavily refactored to fix some long outstanding issues.

- Error callbacks can now take real exception and traceback instances (Issue #2538).

```python
>>> add.s(2, 2).on_error(log_error.s()).delay()
```

Where `log_error` could be defined as:

```python
@app.task
def log_error(request, exc, traceback):
    with open(os.path.join('/var/errors', request.id), 'a') as fh:
        print('--

{0} {1} {2}'.format(task_id, exc, traceback), file=fh)
```

See *Canvas: Designing Work-flows* for more examples.

- `chain(a, b, c)` now works the same as `a | b | c`.

  This means chain may no longer return an instance of `chain`, instead it may optimize the workflow so that e.g. two groups chained together becomes one group.

- Now unrolls groups within groups into a single group (Issue #1509).
- `chunks/map/starmap` tasks now routes based on the target task
- `chords` and `chains` can now be immutable.
- Fixed bug where serialized signatures weren’t converted back into signatures (Issue #2078)

  Fix contributed by Ross Deane.
- Fixed problem where chains and groups didn’t work when using JSON serialization (Issue #2076).

  Fix contributed by Ross Deane.
- Creating a chord no longer results in multiple values for keyword argument ‘task_id’ (Issue #2225).

  Fix contributed by Aneil Mallavarapu.
- Fixed issue where the wrong result is returned when a chain contains a chord as the penultimate task.

  Fix contributed by Aneil Mallavarapu.
- Special case of `group(A.s() | group(B.s() | C.s()))` now works.
- `chain`: Fixed bug with incorrect id set when a subtask is also a chain.
- `group | group` is now flattened into a single group (Issue #2573).
- Fixed issue where `group | task` wasn’t upgrading correctly to chord (Issue #2922).
- Chords now properly sets `result.parent` links.
- `chunks/map/starmap` are now routed based on the target task.
- **Signature .link now works when argument is scalar (not a list)** (Issue #2019).
- `group()` now properly forwards keyword arguments (Issue #3426).

  Fix contributed by Samuel Giffard.
- A `chord` where the header group only consists of a single task is now turned into a simple chain.
- Passing a `link` argument to `group.apply_async()` now raises an error (Issue #3508).
• `chord | sig` now attaches to the chord callback (Issue #3356).

## Periodic Tasks

### New API for configuring periodic tasks

This new API enables you to use signatures when defining periodic tasks, removing the chance of mistyping task names.

An example of the new API is [here](#).

### Optimized Beat implementation

The `celery beat` implementation has been optimized for millions of periodic tasks by using a heap to schedule entries.

Contributed by [Ask Solem](#) and [Alexander Koshelev](#).

### Schedule tasks based on sunrise, sunset, dawn and dusk

See [Solar schedules](#) for more information.

Contributed by [Mark Parncutt](#).

## Result Backends

### RPC Result Backend matured

Lots of bugs in the previously experimental RPC result backend have been fixed and can now be considered to production use.

Contributed by [Ask Solem](#), [Morris Tweed](#).

### Redis: Result backend optimizations

`result.get()` is now using pub/sub for streaming task results

Calling `result.get()` when using the Redis result backend used to be extremely expensive as it was using polling to wait for the result to become available. A default polling interval of 0.5 seconds didn’t help performance, but was necessary to avoid a spin loop.

The new implementation is using Redis Pub/Sub mechanisms to publish and retrieve results immediately, greatly improving task round-trip times.

Contributed by [Yaroslav Zhavoronkov](#) and [Ask Solem](#).
New optimized chord join implementation

This was an experimental feature introduced in Celery 3.1, that could only be enabled by adding `?new_join=1` to the result backend URL configuration.

We feel that the implementation has been tested thoroughly enough to be considered stable and enabled by default. The new implementation greatly reduces the overhead of chords, and especially with larger chords the performance benefit can be massive.

New Riak result backend introduced

See [Riak backend settings](#) for more information.

Contributed by Gilles Dartiguelongue, Alman One and NoKriK.

New CouchDB result backend introduced

See [CouchDB backend settings](#) for more information.

Contributed by Nathan Van Gheem.

New Consul result backend introduced

Add support for Consul as a backend using the Key/Value store of Consul.

Consul has an HTTP API where through you can store keys with their values.

The backend extends KeyValueStoreBackend and implements most of the methods.

Mainly to set, get and remove objects.

This allows Celery to store Task results in the K/V store of Consul.

Consul also allows to set a TTL on keys using the Sessions from Consul. This way the backend supports auto expiry of Task results.

For more information on Consul visit [https://consul.io/](https://consul.io/)

The backend uses python-consul for talking to the HTTP API. This package is fully Python 3 compliant just as this backend is:

```
$ pip install python-consul
```

That installs the required package to talk to Consul’s HTTP API from Python.

You can also specify consul as an extension in your dependency on Celery:

```
$ pip install celery[consul]
```

See [Bundles](#) for more information.

Contributed by Wido den Hollander.
Brand new Cassandra result backend

A brand new Cassandra backend utilizing the new cassandra-driver library is replacing the old result backend using the older pycassa library.

See Cassandra backend settings for more information.

To depend on Celery with Cassandra as the result backend use:

```bash
$ pip install celery[cassandra]
```

You can also combine multiple extension requirements, please see Bundles for more information.

New Elasticsearch result backend introduced

See Elasticsearch backend settings for more information.

To depend on Celery with Elasticsearch as the result backend use:

```bash
$ pip install celery[elasticsearch]
```

You can also combine multiple extension requirements, please see Bundles for more information.

Contributed by Ahmet Demir.

New File-system result backend introduced

See File-system backend settings for more information.

Contributed by Môshe van der Sterre.

Event Batching

Events are now buffered in the worker and sent as a list, reducing the overhead required to send monitoring events.

For authors of custom event monitors there will be no action required as long as you’re using the Python Celery helpers (Receiver) to implement your monitor.

However, if you’re parsing raw event messages you must now account for batched event messages, as they differ from normal event messages in the following way:

- The routing key for a batch of event messages will be set to `<event-group>.multi` where the only batched event group is currently `task` (giving a routing key of `task.multi`).
- The message body will be a serialized list-of-dictionaries instead of a dictionary. Each item in the list can be regarded as a normal event message body.

In Other News…

Requirements

- Now depends on Kombu 4.0.
- Now depends on billiard version 3.5.
- No longer depends on anyjson. Good-bye old friend :(

3.13. History
Tasks

- The “anon-exchange” is now used for simple name-name direct routing.

  This increases performance as it completely bypasses the routing table, in addition it also improves reliability for the Redis broker transport.

- An empty ResultSet now evaluates to True.

  Fix contributed by Colin McIntosh.

- The default routing key (task_default_routing_key) and exchange name (task_default_exchange) is now taken from the task_default_queue setting.

  This means that to change the name of the default queue, you now only have to set a single setting.

- New task_reject_on_worker_lost setting, and reject_on_worker_lost task attribute decides what happens when the child worker process executing a late ack task is terminated.

  Contributed by Michael Permana.

- Task.subtask renamed to Task.signature with alias.

- Task.subtask_from_request renamed to Task.signature_from_request with alias.

- The delivery_mode attribute for kombu.Queue is now respected (Issue #1953).

- Routes in task-routes can now specify a Queue instance directly.

  Example:

  ```python
  task_routes = {'proj.tasks.add': {'queue': Queue('add')}}
  ```

- AsyncResult now raises ValueError if task_id is None. (Issue #1996).

- Retried tasks didn’t forward expires setting (Issue #3297).

- result.get() now supports an on_message argument to set a callback to be called for every message received.

- New abstract classes added:

  - CallableTask

    Looks like a task.

  - CallableSignature

    Looks like a task signature.

- Task.replace now properly forwards callbacks (Issue #2722).

  Fix contributed by Nicolas Unravel.

- Task.replace: Append to chain/chord (Closes #3232)

  Fixed issue #3232, adding the signature to the chain (if there’s any). Fixed the chord suppress if the given signature contains one.

  Fix contributed by @honux.

- Task retry now also throws in eager mode.

  Fix contributed by Feanil Patel.
Beat

- Fixed crontab infinite loop with invalid date.
  
  When occurrence can never be reached (example, April, 31th), trying to reach the next occurrence
  would trigger an infinite loop.
  
  Try fixing that by raising a `RuntimeError` after 2,000 iterations
  
  (Also added a test for crontab leap years in the process)
  
  Fix contributed by Romuald Brunet.

- Now ensures the program exits with a non-zero exit code when an exception terminates the service.
  
  Fix contributed by Simon Peeters.

App

- Dates are now always timezone aware even if `enable_utc` is disabled (Issue #943).
  Fix contributed by Omer Katz.

- `Config`: App preconfiguration is now also pickled with the configuration.
  Fix contributed by Jeremy Zafran.

- The application can now change how task names are generated using the `gen_task_name()` method.
  Contributed by Dmitry Malinovsky.

- App has new `app.current_worker_task` property that returns the task that’s currently being worked on
  (or `None`). (Issue #2100).

Logging

- `get_task_logger()` now raises an exception if trying to use the name “celery” or “celery.task” (Issue
  #3475).

Execution Pools

- `Eventlet/Gevent`: now enables AMQP heartbeat (Issue #3338).

- `Eventlet/Gevent`: Fixed race condition leading to “simultaneous read” errors (Issue #2755).

- Prefork: Prefork pool now uses `poll` instead of `select` where available (Issue #2373).

- Prefork: Fixed bug where the pool would refuse to shut down the worker (Issue #2606).

- `Eventlet`: Now returns pool size in `celery inspect stats` command.
  
  Contributed by Alexander Oblovatniy.

Testing

- Celery is now a `pytest` plugin, including fixtures useful for unit and integration testing.

  See the `testing user guide` for more information.
Transports

• `amqps://` can now be specified to require SSL.
• **Redis Transport**: The Redis transport now supports the `broker_use_ssl` option. Contributed by Robert Kolba.
• JSON serializer now calls `obj.__json__` for unsupported types.
  
  This means you can now define a `__json__` method for custom types that can be reduced down to a built-in json type.
  
  Example:

  ```python
  class Person:
      first_name = None
      last_name = None
      address = None

      def __json__(self):
          return {
              'first_name': self.first_name,
              'last_name': self.last_name,
              'address': self.address,
          }
  ```

• JSON serializer now handles datetime’s, Django promise, UUID and Decimal.
• New `Queue.consumer_arguments` can be used for the ability to set consumer priority via `x-priority`. See https://www.rabbitmq.com/consumer-priority.html
  
  Example:

  ```python
  consumer = Consumer(channel, consumer_arguments={'x-priority': 3})
  ```

• Queue/Exchange: `no_declare` option added (also enabled for internal amq. exchanges).

Programs

• Celery is now using `argparse`, instead of `optparse`.
• All programs now disable colors if the controlling terminal is not a TTY.
• **celery worker**: The `-q` argument now disables the startup banner.
• **celery worker**: The “worker ready” message is now logged using severity info, instead of warn.
• **celery multi**: `%n` format for is now synonym with `%N` to be consistent with `celery worker`.
• **celery inspect/celery control**: now supports a new `--json` option to give output in json format.
• **celery inspect registered**: now ignores built-in tasks.
• **celery purge** now takes `-Q` and `-X` options used to specify what queues to include and exclude from the purge.
• New **celery logtool**: Utility for filtering and parsing celery worker log-files
• **celery multi**: now passes through `%i` and `%f` log file formats.
• General: `%p` can now be used to expand to the full worker node-name in log-file/pid-file arguments.
• A new command line option `--executable` is now available for daemonizing programs (`celery worker` and `celery beat`).

  Contributed by Bert Vanderbauwhede.

• `celery worker`: supports new `--prefetch-multiplier` option.

  Contributed by Mickaël Penhard.

• The `--loader` argument is now always effective even if an app argument is set (Issue #3405).

• `inspect/control` now takes commands from registry

  This means user remote-control commands can also be used from the command-line.

  Note that you need to specify the arguments/and type of arguments for the arguments to be correctly passed on the command-line.

  There are now two decorators, which use depends on the type of command: `@inspect_command` + `@control_command`:

  ```python
  from celery.worker.control import control_command
  
  @control_command(
      args=[('n', int)],
      signature='[N=1]',
  )
  def something(state, n=1, **kwargs):
      ...
  ```

  Here `args` is a list of args supported by the command. The list must contain tuples of `(argument_name, type)`.

  `signature` is just the command-line help used in e.g. `celery -A proj control --help`.

  Commands also support `variadic` arguments, which means that any arguments left over will be added to a single variable. Here demonstrated by the `terminate` command which takes a signal argument and a variable number of task_ids:

  ```python
  from celery.worker.control import control_command
  
  @control_command(
      args=[('signal', str)],
      signature='<signal> [id1, [id2, [... , [idN]]]]',
      variadic='ids',
  )
  def terminate(state, signal, ids, **kwargs):
      ...
  ```

  This command can now be called using:

  ```bash
  $ celery -A proj control terminate SIGKILL id1 id2 id3
  ```

  See *Writing your own remote control commands* for more information.

Worker

• Improvements and fixes for `LimitedSet`.  

3.13. History
Getting rid of leaking memory + adding minlen size of the set: the minimal residual size of the set after operating for some time. minlen items are kept, even if they should’ve been expired.

Problems with older and even more old code:

1. Heap would tend to grow in some scenarios (like adding an item multiple times).
2. Adding many items fast wouldn’t clean them soon enough (if ever).
3. When talking to other workers, revoked._data was sent, but it was processed on the other side as iterable. That means giving those keys new (current) time-stamp. By doing this workers could recycle items forever. Combined with 1) and 2), this means that in large set of workers, you’re getting out of memory soon.

All those problems should be fixed now.

This should fix issues #3095, #3086.

Contributed by David Pravec.

- New settings to control remote control command queues.
  - `control_queue_expires`
    Set queue expiry time for both remote control command queues, and remote control reply queues.
  - `control_queue_ttl`
    Set message time-to-live for both remote control command queues, and remote control reply queues.

Contributed by Alan Justino.

- The `worker_shutdown` signal is now always called during shutdown.
  Previously it would not be called if the worker instance was collected by gc first.

- Worker now only starts the remote control command consumer if the broker transport used actually supports them.

- Gossip now sets `x-message-ttl` for event queue to heartbeat_interval s. (Issue #2005).

- Now preserves exit code (Issue #2024).

- Now rejects messages with an invalid ETA value (instead of ack, which means they will be sent to the dead-letter exchange if one is configured).

- Fixed crash when the `-purge` argument was used.

- Log-level for unrecoverable errors changed from `error` to `critical`.

- Improved rate limiting accuracy.

- Account for missing timezone information in task expires field.

  Fix contributed by Albert Wang.

- The worker no longer has a Queues bootsteps, as it is now superfluous.

- Now emits the “Received task” line even for revoked tasks. (Issue #3155).

- Now respects `broker_connection_retry` setting.

  Fix contributed by Nat Williams.

- New `control_queue_ttl` and `control_queue_expires` settings now enables you to configure remote control command message TTLs, and queue expiry time.
Contributed by **Alan Justino**.

- New `celery.worker.state.requests` enables O(1) lookup of active/reserved tasks by id.
- Auto-scale didn’t always update keep-alive when scaling down.
  Fix contributed by **Philip Garnero**.
- Fixed typo `options_list` -> `option_list`.
  Fix contributed by **Greg Wilbur**.
- Some worker command-line arguments and `Worker()` class arguments have been renamed for consistency.
  All of these have aliases for backward compatibility.
    - `--send-events` -> `--task-events`
    - `--schedule` -> `--schedule-filename`
    - `--maxtasksperchild` -> `--max-tasks-per-child`
    - `Beat(scheduler_cls=)` -> `Beat(scheduler=)`
    - `Worker(send_events=True)` -> `Worker(task_events=True)`
    - `Worker(task_time_limit=)` -> `Worker(time_limit=)`
    - `Worker(task_soft_time_limit=)` -> `Worker(soft_time_limit=)`
    - `Worker(state_db=)` -> `Worker(statedb=)`
    - `Worker(working_directory=)` -> `Worker(workdir=)`

**Debugging Utilities**

- `celery.contrib.rdb`: Changed remote debugger banner so that you can copy and paste the address easily (no longer has a period in the address).
  Contributed by **Jonathan Vanasco**.
- Fixed compatibility with recent psutil versions (Issue #3262).

**Signals**

- **App**: New signals for app configuration/finalization:
  - `app.on_configure`
  - `app.on_after_configure`
  - `app.on_after_finalize`
- **Task**: New task signals for rejected task messages:
  - `celery.signals.task_rejected`
  - `celery.signals.task_unknown`
- **Worker**: New signal for when a heartbeat event is sent.
  - `celery.signals.heartbeat_sent`
  Contributed by **Kevin Richardson**.
Events

- Event messages now uses the RabbitMQ `x-message-ttl` option to ensure older event messages are discarded.
  
  The default is 5 seconds, but can be changed using the `event_queue_ttl` setting.
- `Task.send_event` now automatically retries sending the event on connection failure, according to the task publish retry settings.
- Event monitors now sets the `event_queue Expires` setting by default.
  
  The queues will now expire after 60 seconds after the monitor stops consuming from it.
- Fixed a bug where a None value wasn’t handled properly.
  
  Fix contributed by Dongweiming.
- New `event_queue_prefix` setting can now be used to change the default `celeryev` queue prefix for event receiver queues.
  
  Contributed by Takeshi Kanemoto.
- `State.tasks_by_type` and `State.tasks_by_worker` can now be used as a mapping for fast access to this information.

Deployment

- Generic init-scripts now support `CELERY_SU` and `CELERYD_SU_ARGS` environment variables to set the path and arguments for `su (su(1)).`
- Generic init-scripts now better support FreeBSD and other BSD systems by searching `/usr/local/etc/` for the configuration file.
  
  Contributed by Taha Jahangir.
- Generic init-script: Fixed strange bug for `celerybeat` where restart didn’t always work (Issue #3018).
- The systemd init script now uses a shell when executing services.
  
  Contributed by Tomas Machalek.

Result Backends

- Redis: Now has a default socket timeout of 120 seconds.
  
  The default can be changed using the new `redis_socket_timeout` setting.
  
  Contributed by Raghuram Srinivasan.
- RPC Backend result queues are now auto delete by default (Issue #2001).
- RPC Backend: Fixed problem where exception wasn’t deserialized properly with the json serializer (Issue #2518).
  
  Fix contributed by Allard Hoeve.
- CouchDB: The backend used to double-json encode results.
  
  Fix contributed by Andrew Stewart.
- CouchDB: Fixed typo causing the backend to not be found (Issue #3287).
Fix contributed by Andrew Stewart.

- **MongoDB**: Now supports setting the `result_serializer` setting to `bson` to use the MongoDB libraries own serializer.
  Contributed by Davide Quarta.

- **MongoDB**: URI handling has been improved to use database name, user and password from the URI if provided.
  Contributed by Samuel Jaillet.

- **SQLAlchemy result backend**: Now ignores all result engine options when using NullPool (Issue #1930).

- **SQLAlchemy result backend**: Now sets max char size to 155 to deal with brain damaged MySQL Unicode implementation (Issue #1748).

- **General**: All Celery exceptions/warnings now inherit from common `CeleryError/CeleryWarning`. (Issue #2643).

**Documentation Improvements**

Reorganization, Deprecations, and Removals

Incompatible changes

- Prefork: Calling `result.get()` or joining any result from within a task now raises `RuntimeError`. In previous versions this would emit a warning.
- `celery.worker.consumer` is now a package, not a module.
- Module `celery.worker.job` renamed to `celery.worker.request`.
- Result: The `task_name` argument/attribute of `appAsyncResult` was removed. This was historically a field used for `pickle` compatibility, but is no longer needed.
- Backends: Arguments named `status` renamed to `state`.
- Backends: `backend.get_status()` renamed to `backend.get_state()`.
- Backends: `backend.maybe_reraise()` renamed to `.maybe_throw()`.

The promise API uses `.throw()`, so this change was made to make it more consistent.

There’s an alias available, so you can still use maybe_reraise until Celery 5.0.

Unscheduled Removals

- The experimental `celery.contrib.methods` feature has been removed, as there were far many bugs in the implementation to be useful.
- The CentOS init-scripts have been removed.

These didn’t really add any features over the generic init-scripts, so you’re encouraged to use them instead, or something like `supervisor`.

Reorganization Deprecations

These symbols have been renamed, and while there’s an alias available in this version for backward compatibility, they will be removed in Celery 5.0, so make sure you rename these ASAP to make sure it won’t break for that release.

Chances are that you’ll only use the first in this list, but you never know:

- `celery.utils.worker_direct` -> `celery.utils.nodenames.worker_direct()`.
- `celery.utils.nodename` -> `celery.utils.nodenames.nodename()`.
- `celery.utils.anon_nodename` -> `celery.utils.nodenames.anon_nodename()`.
- `celery.utils.nodesplit` -> `celery.utils.nodenames.nodesplit()`.
- `celery.utils.default_nodename` -> `celery.utils.nodenames.default_nodename()`.
- `celery.utils.node_format` -> `celery.utils.nodenames.node_format()`.
- `celery.utils.host_format` -> `celery.utils.nodenames.host_format()`.
Scheduled Removals

Modules

- Module `celery.worker.job` has been renamed to `celery.worker.request`.
  This was an internal module so shouldn’t have any effect. It’s now part of the public API so must not change again.

- Module `celery.task.trace` has been renamed to `celery.app.trace` as the `celery.task` package is being phased out. The module will be removed in version 5.0 so please change any import from:

  ```python
  from celery.task.trace import X
  ```

to:

  ```python
  from celery.app.trace import X
  ```

- Old compatibility aliases in the `celery.loaders` module has been removed.
  - Removed `celery.loaders.current_loader()`, use: `current_app.loader`
  - Removed `celery.loaders.load_settings()`, use: `current_app.conf`

Result

- `AsyncResult.serializable()` and `celery.result.from_serializable` has been removed:
  Use instead:

  ```python
  >>> tup = result.as_tuple()
  >>> from celery.result import result_from_tuple
  >>> result = result_from_tuple(tup)
  ```

- Removed `BaseAsyncResult`, use `AsyncResult` for instance checks instead.
- Removed `TaskSetResult`, use `GroupResult` instead.
  - `TaskSetResult.total` -> `len(GroupResult)`
  - `TaskSetResult.taskset_id` -> `GroupResult.id`
- Removed `ResultSet.subtasks`, use `ResultSet.results` instead.

TaskSet

TaskSet has been removed, as it was replaced by the `group` construct in Celery 3.0.

If you have code like this:

```python
>>> from celery.task import TaskSet
>>> TaskSet(add.subtask((i, i)) for i in xrange(10)).apply_async()
```

You need to replace that with:

```python
>>> from celery import group
>>> group(add.s(i, i) for i in xrange(10))()
```
Events

- **Removals for class `celery.events.state.Worker`:**
  - Worker._defaults attribute.
    
    Use `\{k: getattr(worker, k) for k in worker._fields\}`.
  - Worker.update_heartbeat
    
    Use `Worker.event(None, timestamp, received)`.
  - Worker.on_online
    
    Use `Worker.event('online', timestamp, received, fields)`.
  - Worker.on_offline
    
    Use `Worker.event('offline', timestamp, received, fields)`.
  - Worker.on_heartbeat
    
    Use `Worker.event('heartbeat', timestamp, received, fields)`.

- **Removals for class `celery.events.state.Task`:**
  - Task._defaults attribute.
    
    Use `\{k: getattr(task, k) for k in task._fields\}`.
  - Task.on_sent
    
    Use `Task.event('sent', timestamp, received, fields)`.
  - Task.on_received
    
    Use `Task.event('received', timestamp, received, fields)`.
  - Task.on_started
    
    Use `Task.event('started', timestamp, received, fields)`.
  - Task.on_failed
    
    Use `Task.event('failed', timestamp, received, fields)`.
  - Task.on_retried
    
    Use `Task.event('retried', timestamp, received, fields)`.
  - Task.on_succeeded
    
    Use `Task.event('succeeded', timestamp, received, fields)`.
  - Task.on_revoked
    
    Use `Task.event('revoked', timestamp, received, fields)`.
  - Task.on_unknown_event
    
    Use `Task.event(short_type, timestamp, received, fields)`.
  - Task.update
    
    Use `Task.event(short_type, timestamp, received, fields)`.
  - Task.merge
    
    Use `Task.event(short_type, timestamp, received, fields)`.

Contact us if you need this.
Magic keyword arguments

Support for the very old magic keyword arguments accepted by tasks is finally removed in this version.

If you’re still using these you have to rewrite any task still using the old `celery.decorators` module and depending on keyword arguments being passed to the task, for example:

```python
from celery.decorators import task
@task()
def add(x, y, task_id=None):
    print('My task id is %r' % (task_id,))
```

should be rewritten into:

```python
from celery import task
@task(bind=True)
def add(self, x, y):
    print('My task id is {0.request.id}'.format(self))
```

Removed Settings

The following settings have been removed, and is no longer supported:

### Logging Settings

<table>
<thead>
<tr>
<th>Setting name</th>
<th>Replace with</th>
</tr>
</thead>
<tbody>
<tr>
<td>CELERYD_LOG_LEVEL</td>
<td><code>celery worker --loglevel</code></td>
</tr>
<tr>
<td>CELERYD_LOG_FILE</td>
<td><code>celery worker --logfile</code></td>
</tr>
<tr>
<td>CELERYBEAT_LOG_LEVEL</td>
<td><code>celery beat --loglevel</code></td>
</tr>
<tr>
<td>CELERYBEAT_LOG_FILE</td>
<td><code>celery beat --logfile</code></td>
</tr>
<tr>
<td>CELERYMON_LOG_LEVEL</td>
<td><code>celerymon is deprecated, use flower</code></td>
</tr>
<tr>
<td>CELERYMON_LOG_FILE</td>
<td><code>celerymon is deprecated, use flower</code></td>
</tr>
<tr>
<td>CELERYMON_LOG_FORMAT</td>
<td><code>celerymon is deprecated, use flower</code></td>
</tr>
</tbody>
</table>

### Task Settings

<table>
<thead>
<tr>
<th>Setting name</th>
<th>Replace with</th>
</tr>
</thead>
<tbody>
<tr>
<td>CELERY_CHORD_PROPAGATES</td>
<td>N/A</td>
</tr>
</tbody>
</table>

Changes to internal API

- Module `celery.datastructures` renamed to `celery.utils.collections`.
- Module `celery.utils.timeutils` renamed to `celery.utils.time`.
- `celery.utils.datastructures.DependencyGraph` moved to `celery.utils.graph`.
- `celery.utils.jsonify` is now `celery.utils.serialization.jsonify()`.
• celery.utils.strtobool is now celery.utils.serialization.strtobool().
• celery.utils.is_iterable has been removed.
    Instead use:
    ```python
isinstance(x, collections.Iterable)
```
• celery.utils.lpmerge is now celery.utils.collections.lpmerge().
• celery.utils.cry is now celery.utils.debug.cry().
• celery.utils.isatty is now celery.platforms.isatty().
• celery.utils.gen_task_name is now celery.utils.imports.gen_task_name().
• celery.utils.deprecated is now celery.utils.deprecated.Callable()
• celery.utils.deprecated_property is now celery.utils.deprecated.Property().
• celery.utils.warn_deprecated is now celery.utils.deprecated.warn()

Deprecation Time-line Changes

See the Celery Deprecation Time-line.

### 3.13.6 Change history

This document contains change notes for bugfix releases in the 4.0.x series (latentcall), please see What’s new in Celery 4.0 (latentcall) for an overview of what’s new in Celery 4.0.

#### 4.0.2

- **release-date** 2016-12-15 03:40 PM PST
- **release-by** Ask Solem

- **Requirements**
  - Now depends on Kombu 4.0.2.

- **Tasks**: Fixed problem with JSON serialization of group (keys must be string error, Issue #3688).

- **Worker**: Fixed JSON serialization issue when using inspect active and friends (Issue #3667).

- **App**: Fixed saferef errors when using signals (Issue #3670).

- **Prefork**: Fixed bug with pack requiring bytes argument on Python 2.7.5 and earlier (Issue #3674).

- **Tasks**: Saferepr did not handle unicode in bytestrings on Python 2 (Issue #3676).

- **Testing**: Added new celery_worker_paremeters fixture.

  Contributed by Michael Howitz.

- **Tasks**: Added new app argument to GroupResult.restore (Issue #3669).

  This makes the restore method behave the same way as the GroupResult constructor.

  Contributed by Andreas Pelme.

- **Tasks**: Fixed type checking crash when task takes *args on Python 3 (Issue #3678).
• Documentation and examples improvements by:
  – BLAGA Razvan-Paul
  – Michael Howitz
  – @paradox41

4.0.1

release-date 2016-12-08 05:22 PM PST
release-by Ask Solem

• [Security: CELERYSA-0003] Insecure default configuration
  
  The default accept_content setting was set to allow deserialization of pickled messages in Celery 4.0.0.
  
  The insecure default has been fixed in 4.0.1, and you can also configure the 4.0.0 version to explicitly only allow json serialized messages:

  ```
  app.conf.accept_content = ['json']
  ```

• Tasks: Added new method to register class-based tasks (Issue #3615).
  
  To register a class based task you should now call `app.register_task`:

  ```python
  from celery import Celery, Task
  app = Celery()

  class CustomTask(Task):
    def run(self):
      return 'hello'

  app.register_task(CustomTask())
  ```

• Tasks: Argument checking now supports keyword-only arguments on Python3 (Issue #3658).
  
  Contributed by @sww.

• Tasks: The task-sent event was not being sent even if configured to do so (Issue #3646).

• Worker: Fixed AMQP heartbeat support for eventlet/gevent pools (Issue #3649).

• App: `app.conf.humanize()` would not work if configuration not finalized (Issue #3652).

• Utils: `saferepr` attempted to show iterables as lists and mappings as dicts.

• Utils: `saferepr` did not handle unicode-errors when attempting to format `bytes` on Python 3 (Issue #3610).

• Utils: `saferepr` should now properly represent byte strings with non-ascii characters (Issue #3600).

• Results: Fixed bug in elasticsearch where _index method missed the body argument (Issue #3606).
  
  Fix contributed by (Sean Ho).

• Canvas: Fixed `ValueError` in chord with single task header (Issue #3608).
  
  Fix contributed by Viktor Holmqvist.

• Task: Ensure class-based task has name prior to registration (Issue #3616).
• **Beat:** Fixed problem with strings in shelve (Issue #3644).
  Fix contributed by Alli.

• **Worker:** Fixed `KeyError` in `inspect_stats` when `-O` argument set to something other than `fast` or `fair` (Issue #3621).

• **Task:** Retried tasks were no longer sent to the original queue (Issue #3622).

• **Worker:** Python 3: Fixed None/int type comparison in `apps/worker.py` (Issue #3631).

• **Results:** Redis has a new `redis_socket_connect_timeout` setting.

• **Results:** Redis result backend passed the `socket_connect_timeout` argument to UNIX socket based connections by mistake, causing a crash.

• **Worker:** Fixed missing logo in worker splash screen when running on Python 3.x (Issue #3627).
  Fix contributed by Brian Luan.

• **Deps:** Fixed `celery[redis]` bundle installation (Issue #3643).
  Fix contributed by Rémi Marenco.

• **Deps:** Bundle `celery[sqs]` now also requires `pycurl` (Issue #3619).

• **Worker:** Hard time limits were no longer being respected (Issue #3618).

• **Worker:** Soft time limit log showed `Trues` instead of the number of seconds.

• **App:** `registry_cls` argument no longer had any effect (Issue #3613).

• **Worker:** Event producer now uses `connection_for_Write` (Issue #3525).

• **Results:** Redis/memcache backends now uses `result_expires` to expire chord counter (Issue #3573).
  Contributed by Tayfun Sen.

• **Django:** Fixed command for upgrading settings with Django (Issue #3563).
  Fix contributed by François Voron.

• **Testing:** Added a `celery_parameters` test fixture to be able to use customized Celery init parameters. (#3626)
  Contributed by Steffen Allner.

4.0.0

**release-date** 2016-11-04 02:00 P.M PDT

**release-by** Ask Solem

See *What’s new in Celery 4.0 (latentcall)* (in `docs/whatsnew-4.0.rst`).

4.0.0rc7

**release-date** 2016-11-02 01:30 P.M PDT

**Important notes**

- Database result backend related setting names changed from `sqlalchemy_*` -> `database_*`.
  The `sqlalchemy_` named settings won’t work at all in this version so you need to rename them. This is a last minute change, and as they were not supported in 3.1 we will not be providing aliases.

- `chain(A, B, C)` now works the same way as `A | B | C`.
  This means calling `chain()` might not actually return a chain, it can return a group or any other type depending on how the workflow can be optimized.

3.13.7 *What’s new in Celery 3.1 (Cipater)*

**Author** Ask Solem ([ask at celeryproject.org](mailto:ask@celeryproject.org))

**Change history**

What’s new documents describe the changes in major versions, we also have a *Change history* that lists the changes in bugfix releases (0.0.x), while older series are archived under the *History* section.

Celery is a simple, flexible, and reliable distributed system to process vast amounts of messages, while providing operations with the tools required to maintain such a system.

It’s a task queue with focus on real-time processing, while also supporting task scheduling.

Celery has a large and diverse community of users and contributors, you should come join us on IRC or our mailing-list.

To read more about Celery you should go read the *introduction*.

While this version is backward compatible with previous versions it’s important that you read the following section.

This version is officially supported on CPython 2.6, 2.7, and 3.3, and also supported on PyPy.

**Table of Contents**

Make sure you read the important notes before upgrading to this version.
Preface

Deadlocks have long plagued our workers, and while uncommon they’re not acceptable. They’re also infamous for being extremely hard to diagnose and reproduce, so to make this job easier I wrote a stress test suite that bombards the worker with different tasks in an attempt to break it.

What happens if thousands of worker child processes are killed every second? what if we also kill the broker connection every 10 seconds? These are examples of what the stress test suite will do to the worker, and it reruns these tests using different configuration combinations to find edge case bugs.

The end result was that I had to rewrite the prefork pool to avoid the use of the POSIX semaphore. This was extremely challenging, but after months of hard work the worker now finally passes the stress test suite.

There’s probably more bugs to find, but the good news is that we now have a tool to reproduce them, so should you be so unlucky to experience a bug then we’ll write a test for it and squash it!
Note that I’ve also moved many broker transports into experimental status: the only transports recommended for production use today is RabbitMQ and Redis.

I don’t have the resources to maintain all of them, so bugs are left unresolved. I wish that someone will step up and take responsibility for these transports or donate resources to improve them, but as the situation is now I don’t think the quality is up to date with the rest of the code-base so I cannot recommend them for production use.

The next version of Celery 4.0 will focus on performance and removing rarely used parts of the library. Work has also started on a new message protocol, supporting multiple languages and more. The initial draft can be found [here](#).

This has probably been the hardest release I’ve worked on, so no introduction to this changelog would be complete without a massive thank you to everyone who contributed and helped me test it!

Thank you for your support!

— Ask Solem

### Important Notes

#### Dropped support for Python 2.5

Celery now requires Python 2.6 or later.

The new dual code base runs on both Python 2 and 3, without requiring the `2to3` porting tool.

**Note:** This is also the last version to support Python 2.6! From Celery 4.0 and on-wards Python 2.7 or later will be required.

#### Last version to enable Pickle by default

Starting from Celery 4.0 the default serializer will be json.

If you depend on pickle being accepted you should be prepared for this change by explicitly allowing your worker to consume pickled messages using the `CELERY_ACCEPT_CONTENT` setting:

```python
CELERY_ACCEPT_CONTENT = ['pickle', 'json', 'msgpack', 'yaml']
```

Make sure you only select the serialization formats you’ll actually be using, and make sure you’ve properly secured your broker from unwanted access (see the [Security Guide](#)).

The worker will emit a deprecation warning if you don’t define this setting.

**for Kombu users**

Kombu 3.0 no longer accepts pickled messages by default, so if you use Kombu directly then you have to configure your consumers: see the Kombu 3.0 Changelog for more information.

#### Old command-line programs removed and deprecated

Everyone should move to the new `celery` umbrella command, so we’re incrementally deprecating the old command names.

In this version we’ve removed all commands that aren’t used in init-scripts. The rest will be removed in 4.0.
<table>
<thead>
<tr>
<th>Program</th>
<th>New Status</th>
<th>Replacement</th>
</tr>
</thead>
<tbody>
<tr>
<td>celeryd</td>
<td>DEPRECATED</td>
<td>celery worker</td>
</tr>
<tr>
<td>celerybeat</td>
<td>DEPRECATED</td>

</tr>
<tr>
<td>celeryev</td>
<td>REMOVED</td>
<td>celery events</td>
</tr>
<tr>
<td>camqadm</td>
<td>REMOVED</td>
<td>celery amqp</td>
</tr>
</tbody>
</table>

If this isn’t a new installation then you may want to remove the old commands:

```bash
$ pip uninstall celery
$ # repeat until it fails
# ...
$ pip uninstall celery
$ pip install celery
```

Please run `celery --help` for help using the umbrella command.

### News

#### Prefork Pool Improvements

These improvements are only active if you use an async capable transport. This means only RabbitMQ (AMQP) and Redis are supported at this point and other transports will still use the thread-based fallback implementation.

- **Pool is now using one IPC queue per child process.**

  Previously the pool shared one queue between all child processes, using a POSIX semaphore as a mutex to achieve exclusive read and write access.

  The POSIX semaphore has now been removed and each child process gets a dedicated queue. This means that the worker will require more file descriptors (two descriptors per process), but it also means that performance is improved and we can send work to individual child processes.

  POSIX semaphores aren’t released when a process is killed, so killing processes could lead to a deadlock if it happened while the semaphore was acquired. There’s no good solution to fix this, so the best option was to remove the semaphore.

- **Asynchronous write operations**

  The pool now uses async I/O to send work to the child processes.

- **Lost process detection is now immediate.**

  If a child process is killed or exits mysteriously the pool previously had to wait for 30 seconds before marking the task with a `WorkerLostError`. It had to do this because the out-queue was shared between all processes, and the pool couldn’t be certain whether the process completed the task or not. So an arbitrary timeout of 30 seconds was chosen, as it was believed that the out-queue would’ve been drained by this point.

  This timeout is no longer necessary, and so the task can be marked as failed as soon as the pool gets the notification that the process exited.

- **Rare race conditions fixed**

  Most of these bugs were never reported to us, but were discovered while running the new stress test suite.
Caveats

Long running tasks

The new pool will send tasks to a child process as long as the process in-queue is writable, and since the socket is buffered this means that the processes are, in effect, prefetching tasks.

This benefits performance but it also means that other tasks may be stuck waiting for a long running task to complete:

```
-> send T1 to Process A
# A executes T1
-> send T2 to Process B
# B executes T2
<- T2 complete

-> send T3 to Process A
# A still executing T1, T3 stuck in local buffer and
# won't start until T1 returns
```

The buffer size varies based on the operating system: some may have a buffer as small as 64KB but on recent Linux versions the buffer size is 1MB (can only be changed system wide).

You can disable this prefetching behavior by enabling the `-Ofair` worker option:

```
$ celery -A proj worker -l info -Ofair
```

With this option enabled the worker will only write to workers that are available for work, disabling the prefetch behavior.

Max tasks per child

If a process exits and pool prefetch is enabled the worker may have already written many tasks to the process in-queue, and these tasks must then be moved back and rewritten to a new process.

This is very expensive if you have the `--max-tasks-per-child` option set to a low value (e.g., less than 10), you should not be using the `-Ofast` scheduler option.

Django supported out of the box

Celery 3.0 introduced a shiny new API, but unfortunately didn’t have a solution for Django users.

The situation changes with this version as Django is now supported in core and new Django users coming to Celery are now expected to use the new API directly.

The Django community has a convention where there’s a separate `django-x` package for every library, acting like a bridge between Django and the library.

Having a separate project for Django users has been a pain for Celery, with multiple issue trackers and multiple documentation sources, and then lastly since 3.0 we even had different APIs.

With this version we challenge that convention and Django users will use the same library, the same API and the same documentation as everyone else.

There’s no rush to port your existing code to use the new API, but if you’d like to experiment with it you should know that:
• You need to use a Celery application instance.

The new Celery API introduced in 3.0 requires users to instantiate the library by creating an application:

```python
from celery import Celery
app = Celery()
```

• You need to explicitly integrate Celery with Django

Celery won’t automatically use the Django settings, so you can either configure Celery separately or you can tell it to use the Django settings with:

```python
app.config_from_object('django.conf:settings')
```

Neither will it automatically traverse your installed apps to find task modules. If you want this behavior, you must explicitly pass a list of Django instances to the Celery app:

```python
from django.conf import settings
app.autodiscover_tasks(lambda: settings.INSTALLED_APPS)
```

• You no longer use manage.py

Instead you use the `celery` command directly:

```
$ celery -A proj worker -l info
```

For this to work your app module must store the `DJANGO_SETTINGS_MODULE` environment variable, see the example in the Django guide.

To get started with the new API you should first read the First Steps with Celery tutorial, and then you should read the Django-specific instructions in First steps with Django.

The fixes and improvements applied by the django-celery library are now automatically applied by core Celery when it detects that the `DJANGO_SETTINGS_MODULE` environment variable is set.

The distribution ships with a new example project using Django in examples/django:

https://github.com/celery/celery/tree/3.1/examples/django

Some features still require the django-celery library:

• Celery doesn’t implement the Django database or cache result backends.

• **Celery doesn’t ship with the database-based periodic task** scheduler.

**Note:** If you’re still using the old API when you upgrade to Celery 3.1 then you must make sure that your settings module contains the `djcelery.setup_loader()` line, since this will no longer happen as a side-effect of importing the `django-celery` module.

New users (or if you’ve ported to the new API) don’t need the `setup_loader` line anymore, and must make sure to remove it.

---

**Events are now ordered using logical time**

Keeping physical clocks in perfect sync is impossible, so using time-stamps to order events in a distributed system isn’t reliable.
Celery event messages have included a logical clock value for some time, but starting with this version that field is also used to order them.

Also, events now record timezone information by including a new `utcoffset` field in the event message. This is a signed integer telling the difference from UTC time in hours, so for example, an event sent from the Europe/London timezone in daylight savings time will have an offset of 1.

`app.events.Receiver` will automatically convert the time-stamps to the local timezone.

**Note:** The logical clock is synchronized with other nodes in the same cluster (neighbors), so this means that the logical epoch will start at the point when the first worker in the cluster starts.

If all of the workers are shutdown the clock value will be lost and reset to 0. To protect against this, you should specify the `celery worker --statedb` option such that the worker can persist the clock value at shutdown.

You may notice that the logical clock is an integer value and increases very rapidly. Don’t worry about the value overflowing though, as even in the most busy clusters it may take several millennium before the clock exceeds a 64 bits value.

### New worker node name format (`name@host`)

Node names are now constructed by two elements: name and host-name separated by ‘@’.

This change was made to more easily identify multiple instances running on the same machine.

If a custom name isn’t specified then the worker will use the name ‘celery’ by default, resulting in a fully qualified node name of ‘celery@hostname’:

```
$ celery worker -n example.com
celery@example.com
```

To also set the name you must include the @:

```
$ celery worker -n worker1@example.com
worker1@example.com
```

The worker will identify itself using the fully qualified node name in events and broadcast messages, so where before a worker would identify itself as ‘worker1.example.com’, it’ll now use ‘celery@worker1.example.com’.

Remember that the `-n` argument also supports simple variable substitutions, so if the current host-name is `george.example.com` then the `%h` macro will expand into that:

```
$ celery worker -n worker1@%h
worker1@george.example.com
```

The available substitutions are as follows:

<table>
<thead>
<tr>
<th>Variable</th>
<th>Substitution</th>
</tr>
</thead>
<tbody>
<tr>
<td>%h</td>
<td>Full host-name (including domain name)</td>
</tr>
<tr>
<td>%d</td>
<td>Domain name only</td>
</tr>
<tr>
<td>%n</td>
<td>Host-name only (without domain name)</td>
</tr>
<tr>
<td>%%</td>
<td>The character %</td>
</tr>
</tbody>
</table>
Bound tasks

The task decorator can now create “bound tasks”, which means that the task will receive the self argument.

```python
@app.task(bind=True)
def send_twitter_status(self, oauth, tweet):
    try:
        twitter = Twitter(oauth)
        twitter.update_status(tweet)
    except (Twitter.FailWhaleError, Twitter.LoginError) as exc:
        raise self.retry(exc=exc)
```

Using *bound tasks* is now the recommended approach whenever you need access to the task instance or request context. Previously one would’ve to refer to the name of the task instead (`send_twitter_status.retry`), but this could lead to problems in some configurations.

Mingle: Worker synchronization

The worker will now attempt to synchronize with other workers in the same cluster.

Synchronized data currently includes revoked tasks and logical clock.

This only happens at start-up and causes a one second start-up delay to collect broadcast responses from other workers.

You can disable this bootstep using the `celery worker --without-mingle` option.

Gossip: Worker <-> Worker communication

Workers are now passively subscribing to worker related events like heartbeats.

This means that a worker knows what other workers are doing and can detect if they go offline. Currently this is only used for clock synchronization, but there are many possibilities for future additions and you can write extensions that take advantage of this already.

Some ideas include consensus protocols, reroute task to best worker (based on resource usage or data locality) or restarting workers when they crash.

We believe that although this is a small addition, it opens amazing possibilities.

You can disable this bootstep using the `celery worker --without-gossip` option.

Bootsteps: Extending the worker

By writing bootsteps you can now easily extend the consumer part of the worker to add additional features, like custom message consumers.

The worker has been using bootsteps for some time, but these were never documented. In this version the consumer part of the worker has also been rewritten to use bootsteps and the new *Extensions and Bootsteps* guide documents examples extending the worker, including adding custom message consumers.

See the *Extensions and Bootsteps* guide for more information.

**Note:** Bootsteps written for older versions won’t be compatible with this version, as the API has changed significantly.
The old API was experimental and internal but should you be so unlucky to use it then please contact the mailing-list and we’ll help you port the bootstep to the new API.

New RPC result backend

This new experimental version of the amqp result backend is a good alternative to use in classical RPC scenarios, where the process that initiates the task is always the process to retrieve the result.

It uses Kombu to send and retrieve results, and each client uses a unique queue for replies to be sent to. This avoids the significant overhead of the original amqp result backend which creates one queue per task.

By default results sent using this backend won’t persist, so they won’t survive a broker restart. You can enable the CELERY_RESULT_PERSISTENT setting to change that.

```
CELERY_RESULT_BACKEND = 'rpc'
CELERY_RESULT_PERSISTENT = True
```

Note that chords are currently not supported by the RPC backend.

Time limits can now be set by the client

Two new options have been added to the Calling API: time_limit and soft_time_limit:

```
>>> res = add.apply_async((2, 2), time_limit=10, soft_time_limit=8)
>>> res = add.subtask((2, 2), time_limit=10, soft_time_limit=8).delay()
>>> res = add.s(2, 2).set(time_limit=10, soft_time_limit=8).delay()
```

Contributed by Mher Movsisyan.

Redis: Broadcast messages and virtual hosts

Broadcast messages are currently seen by all virtual hosts when using the Redis transport. You can now fix this by enabling a prefix to all channels so that the messages are separated:

```
BROKER_TRANSPORT_OPTIONS = {'fanout_prefix': True}
```

Note that you’ll not be able to communicate with workers running older versions or workers that doesn’t have this setting enabled.

This setting will be the default in a future version.

Related to Issue #1490.

pytz replaces python-dateutil dependency

Celery no longer depends on the python-dateutil library, but instead a new dependency on the pytz library was added.

The pytz library was already recommended for accurate timezone support.

This also means that dependencies are the same for both Python 2 and Python 3, and that the requirements/default-py3k.txt file has been removed.
Support for setuptools extra requirements

Pip now supports the setuptools extra requirements format, so we’ve removed the old bundles concept, and instead specify setuptools extras.

You install extras by specifying them inside brackets:

```
$ pip install celery[redis,mongodb]
```

The above will install the dependencies for Redis and MongoDB. You can list as many extras as you want.

**Warning:** You can’t use the `celery-with-*` packages anymore, as these won’t be updated to use Celery 3.1.

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

The complete list with examples is found in the *Bundles* section.

**subtask.__call__() now executes the task directly**

A misunderstanding led to `Signature.__call__` being an alias of `.delay` but this doesn’t conform to the calling API of `Task` which calls the underlying task method.

This means that:

```
@app.task
def add(x, y):
    return x + y
add.s(2, 2)()  # Now does the same as calling the task directly:
```

In Other News

- Now depends on Kombu 3.0.
- Now depends on `billiard` version 3.3.
- Worker will now crash if running as the root user with pickle enabled.
- Canvas: `group.apply_async` and `chain.apply_async` no longer starts separate task.
That the group and chord primitives supported the “calling API” like other subtasks was a nice idea, but it was useless in practice and often confused users. If you still want this behavior you can define a task to do it for you.

• New method `Signature.freeze()` can be used to “finalize” signatures/subtask.

Regular signature:

```python
>>> s = add.s(2, 2)
>>> result = s.freeze()
>>> result
<AsyncResult: ffacf44b-f8a1-44e9-80a3-703150151ef2>
>>> s.delay()
<AsyncResult: ffacf44b-f8a1-44e9-80a3-703150151ef2>
```

Group:

```python
>>> g = group(add.s(2, 2), add.s(4, 4))
>>> result = g.freeze()
<GroupResult: e1094bd-08fc-4e14-838e-6d601b99da6d [70c0fb3d-b60e-4b22-8df7-aa25b9abc86d, 58fcd260-2e32-4308-a2ea-f5be4a24f7f4]>
>>> g()
<GroupResult: e1094bd-08fc-4e14-838e-6d601b99da6d [70c0fb3d-b60e-4b22-8df7-aa25b9abc86d, 58fcd260-2e32-4308-a2ea-f5be4a24f7f4]>
```

• Chord exception behavior defined (Issue #1172).

From this version the chord callback will change state to FAILURE when a task part of a chord raises an exception.

See more at Error handling.

• New ability to specify additional command line options to the worker and beat programs.

The `app.user_options` attribute can be used to add additional command-line arguments, and expects optparse-style options:

```python
from celery import Celery
from celery.bin import Option

app = Celery()
app.user_options['worker'].add(
    Option('--my-argument'),
)
```

See the Extensions and Bootsteps guide for more information.

• All events now include a `pid` field, which is the process id of the process that sent the event.

• Event heartbeats are now calculated based on the time when the event was received by the monitor, and not the time reported by the worker.

This means that a worker with an out-of-sync clock will no longer show as ‘Offline’ in monitors.

A warning is now emitted if the difference between the senders time and the internal time is greater than 15 seconds, suggesting that the clocks are out of sync.

• Monotonic clock support.

A monotonic clock is now used for timeouts and scheduling.
The monotonic clock function is built-in starting from Python 3.4, but we also have fallback implementations for Linux and macOS.

• **celery worker** now supports a new `--detach` argument to start the worker as a daemon in the background.

• `app.events.Receiver` now sets a `local_received` field for incoming events, which is set to the time of when the event was received.

• `app.events.Dispatcher` now accepts a `groups` argument which decides a white-list of event groups that’ll be sent.

  The type of an event is a string separated by `-`, where the part before the first `-` is the group. Currently there are only two groups: `worker` and `task`.

  A dispatcher instantiated as follows:

  ```python
  >>> app.events.Dispatcher(connection, groups=['worker'])
  ```

  will only send worker related events and silently drop any attempts to send events related to any other group.

• **New BROKER_FAILOVER_STRATEGY** setting.

  This setting can be used to change the transport fail-over strategy, can either be a callable returning an iterable or the name of a Kombu built-in failover strategy. Default is “round-robin”.

  Contributed by Matt Wise.

• **Result.revoke** will no longer wait for replies.

  You can add the `reply=True` argument if you really want to wait for responses from the workers.

• **Better support for link and link_error tasks for chords.**

  Contributed by Steeve Morin.

• **Worker:** Now emits warning if the `CELERYD_POOL` setting is set to enable the eventlet/gevent pools.

  The `-P` option should always be used to select the eventlet/gevent pool to ensure that the patches are applied as early as possible.

  If you start the worker in a wrapper (like Django’s `manage.py`) then you must apply the patches manually, for example by creating an alternative wrapper that monkey patches at the start of the program before importing any other modules.

• There’s a now an ‘inspect clock’ command which will collect the current logical clock value from workers.

• **celery inspect stats** now contains the process id of the worker’s main process.

  Contributed by Mher Movsisyan.

• **New remote control command to dump a workers configuration.**

  Example:

  ```bash
  $ celery inspect conf
  ```

  Configuration values will be converted to values supported by JSON where possible.

  Contributed by Mher Movsisyan.

• **New settings** `CELERY_EVENT_QUEUE_TTL` and `CELERY_EVENT_QUEUE_EXPIRES`.

  These control when a monitors event queue is deleted, and for how long events published to that queue will be visible. Only supported on RabbitMQ.
• New Couchbase result backend.
  This result backend enables you to store and retrieve task results using Couchbase.
  See Couchbase backend settings for more information about configuring this result backend.
  Contributed by Alain Masiero.
• CentOS init-script now supports starting multiple worker instances.
  See the script header for details.
  Contributed by Jonathan Jordan.
• AsyncResult.iter_native now sets default interval parameter to 0.5
  Fix contributed by Idan Kamara
• New setting BROKER_LOGIN_METHOD.
  This setting can be used to specify an alternate login method for the AMQP transports.
  Contributed by Adrien Guinet
• The dump_conf remote control command will now give the string representation for types that aren’t JSON compatible.
• Function celery.security.setup_security is now app.setup_security().
• Task retry now propagates the message expiry value (Issue #980).
  The value is forwarded at is, so the expiry time won’t change. To update the expiry time you’d’ve to pass a new expires argument to retry().
• Worker now crashes if a channel error occurs.
  Channel errors are transport specific and is the list of exceptions returned by Connection.
  channel_errors. For RabbitMQ this means that Celery will crash if the equivalence checks
  for one of the queues in CELERY_QUEUES mismatches, which makes sense since this is a scenario
  where manual intervention is required.
• Calling AsyncResult.get() on a chain now propagates errors for previous tasks (Issue #1014).
• The parent attribute of AsyncResult is now reconstructed when using JSON serialization (Issue #1014).
• Worker disconnection logs are now logged with severity warning instead of error.
  Contributed by Chris Adams.
• events.State no longer crashes when it receives unknown event types.
• SQLAlchemy Result Backend: New CELERY_RESULT_DB_TABLENAMES setting can be used to change the name of the database tables used.
  Contributed by Ryan Petrello.
• SQLAlchemy Result Backend: Now calls engine.dispose after fork (Issue #1564).
  If you create your own SQLAlchemy engines then you must also make sure that these are
closed after fork in the worker:

```python
from multiprocessing.util import register_after_fork

engine = create_engine(*engine_args)
register_after_fork(engine, engine.dispose)
```
• A stress test suite for the Celery worker has been written.
This is located in the funtests/stress directory in the git repository. There’s a README file there to get you started.

- The logger named celery.concurrency has been renamed to celery.pool.
- New command line utility celery graph.

This utility creates graphs in GraphViz dot format.

You can create graphs from the currently installed bootsteps:

```
# Create graph of currently installed bootsteps in both the worker
# and consumer name-spaces.
$ celery graph bootsteps | dot -T png -o steps.png

# Graph of the consumer name-space only.
$ celery graph bootsteps consumer | dot -T png -o consumer_only.png

# Graph of the worker name-space only.
$ celery graph bootsteps worker | dot -T png -o worker_only.png
```

Or graphs of workers in a cluster:

```
# Create graph from the current cluster
$ celery graph workers | dot -T png -o workers.png

# Create graph from a specified list of workers
$ celery graph workers nodes:w1,w2,w3 | dot -T png workers.png

# also specify the number of threads in each worker
$ celery graph workers nodes:w1,w2,w3 threads:2,4,6

# ...also specify the broker and backend URLs shown in the graph
$ celery graph workers broker:amqp:// backend:redis://

# ...also specify the max number of workers/threads shown (wmax/tmax),
# enumerating anything that exceeds that number.
$ celery graph workers wmax:10 tmax:3
```

- Changed the way that app instances are pickled.

Apps can now define a `__reduce_keys__` method that’s used instead of the old `AppPickler` attribute. For example, if your app defines a custom ‘foo’ attribute that needs to be preserved when pickling you can define a `__reduce_keys__` as such:

```python
import celery

class Celery(celery.Celery):
    def __init__(self, *args, **kwargs):
        super(Celery, self).__init__(*args, **kwargs)
        self.foo = kwargs.get('foo')

    def __reduce_keys__(self):
        return super(Celery, self).__reduce_keys__().update(
            foo=self.foo,
        )
```

This is a much more convenient way to add support for pickling custom attributes. The old `AppPickler` is still supported but its use is discouraged and we would like to remove it in a
future version.

- Ability to trace imports for debugging purposes.
  
  The C_IMPDEBUG can be set to trace imports as they occur:

  $ C_IMDEBUG=1 celery worker -l info

  $ C_IMDEBUG=1 celery shell

- Message headers now available as part of the task request.

  Example adding and retrieving a header value:

  ```python
  @app.task(bind=True)
  def t(self):
      return self.request.headers.get('sender')
  >>> t.apply_async(headers={'sender': 'George Costanza'})
  ```

- New `before_task_publish` signal dispatched before a task message is sent and can be used to modify the final message fields (Issue #1281).
- New `after_task_publish` signal replaces the old `task_sent` signal.
  
  The `task_sent` signal is now deprecated and shouldn’t be used.
- New `worker_process_shutdown` signal is dispatched in the prefork pool child processes as they exit.
  
  Contributed by Daniel M Taub.

- `celery.platforms.PIDFile` renamed to `celery.platforms.Pidfile`.
- MongoDB Backend: Can now be configured using a URL:
- MongoDB Backend: Now disables `auto_start_request`.
- MongoDB Backend: Now enables `use_greenlets` when `eventlet/gevent` is used.
- `subtask()`/`maybe_subtask()` renamed to `signature()`/`maybe_signature()`.
  
  Aliases still available for backwards compatibility.

- The `correlation_id` message property is now automatically set to the id of the task.
- The task message `eta` and `expires` fields now includes timezone information.
- All result backends `store_result/mark_as_*` methods must now accept a `request` keyword argument.
- Events now emit warning if the broken `yajl` library is used.
- The `celeryd_init` signal now takes an extra keyword argument: `option`.
  
  This is the mapping of parsed command line arguments, and can be used to prepare new preload arguments (`app.user_options['preload']`).
- New callback: `app.on_configure()`.
  
  This callback is called when an app is about to be configured (a configuration key is required).
- Worker: No longer forks on `HUP`. 

3.13. History
This means that the worker will reuse the same pid for better support with external process supervisors.

Contributed by Jameel Al-Aziz.

- **Worker**: The log message `Got task from broker ...` was changed to `Received task ....`

- **Worker**: The log message `Skipping revoked task ...` was changed to `Discarding revoked task ....`

- **Optimization**: Improved performance of `ResultSet.join_native()`.

  Contributed by Stas Rudakou.

- The `task_revoked` signal now accepts a new `request` argument (Issue #1555).

  The revoked signal is dispatched after the task request is removed from the stack, so it must instead use the `Request` object to get information about the task.

- **Worker**: New `-X` command line argument to exclude queues (Issue #1399).

  The `-X` argument is the inverse of the `-Q` argument and accepts a list of queues to exclude (not consume from):

  ```
  $C_FAKEFORK=1 celery worker -A proj -l info -X foo
  ```

- Adds `C_FAKEFORK` environment variable for simple init-script/celery multi debugging.

  This means that you can now do:

  ```
  $ C_FAKEFORK=1 celery multi start 10
  ```

  or:

  ```
  $ C_FAKEFORK=1 /etc/init.d/celeryd start
  ```

  to avoid the daemonization step to see errors that aren’t visible due to missing stdout/stderr.

  A `dryrun` command has been added to the generic init-script that enables this option.

- New public API to push and pop from the current task stack:

  ```
  celery.app.push_current_task() and celery.app.pop_current_task()
  ```

- `RetryTaskError` has been renamed to `Retry`.

  The old name is still available for backwards compatibility.

- New semi-predicate exception `Reject`.

  This exception can be raised to `reject/requeue` the task message, see `Reject` for examples.

- `Semipredicates` documented: (Retry/Ignore/Reject).

### Scheduled Removals

- The `BROKER_INSIST` setting and the `insist` argument to `~@connection` is no longer supported.

- The `CELERY_AMQP_TASK_RESULT_CONNECTION_MAX` setting is no longer supported.

  Use `BROKER_POOL_LIMIT` instead.

- The `CELERY_TASK_ERROR_WHITELIST` setting is no longer supported.
You should set the `ErrorMail` attribute of the task class instead. You can also do this using `CELERY_ANNOTATIONS`:

```python
from celery import Celery
from celery.utils.mail import ErrorMail

class MyErrorMail(ErrorMail):
    whitelist = (KeyError, ImportError)

    def should_send(self, context, exc):
        return isinstance(exc, self.whitelist)

app = Celery()
app.conf.CELERY_ANNOTATIONS = {
    '*': {
        'ErrorMail': MyErrorMails,
    }
}
```

- Functions that creates a broker connections no longer supports the `connect_timeout` argument.
  This can now only be set using the `BROKER_CONNECTION_TIMEOUT` setting. This is because functions no longer create connections directly, but instead get them from the connection pool.
- The `CELERY_AMQP_TASK_RESULT_EXPIRES` setting is no longer supported.
  Use `CELERY_TASK_RESULT_EXPIRES` instead.

**Deprecation Time-line Changes**

See the *Celery Deprecation Time-line*.

**Fixes**

- AMQP Backend: `join` didn’t convert exceptions when using the json serializer.
- Non-abstract task classes are now shared between apps (Issue #1150).
  Note that non-abstract task classes shouldn’t be used in the new API. You should only create custom task classes when you use them as a base class in the `@task` decorator.
  This fix ensure backwards compatibility with older Celery versions so that non-abstract task classes works even if a module is imported multiple times so that the app is also instantiated multiple times.
- Worker: Workaround for Unicode errors in logs (Issue #427).
- Task methods: `.apply_async` now works properly if args list is None (Issue #1459).
- Eventlet/gevent/solo/threads pools now properly handles `BaseException` errors raised by tasks.
- `autoscale` and `pool_grow/pool_shrink` remote control commands will now also automatically increase and decrease the consumer prefetch count.
  Fix contributed by Daniel M. Taub.
- `celery control pool_` commands didn’t coerce string arguments to int.
- Redis/Cache chords: Callback result is now set to failure if the group disappeared from the database (Issue #1094).
- Worker: Now makes sure that the shutdown process isn’t initiated more than once.
• Programs: **celery multi** now properly handles both `-f` and `--logfile` options (Issue #1541).

**Internal changes**

• Module `celery.task.trace` has been renamed to `celery.app.trace`.
• Module `celery.concurrency.processes` has been renamed to `celery.concurrency.prefork`.
• Classes that no longer fall back to using the default app:
  – Result backends (`celery.backends.base.BaseBackend`)
  – `celery.worker.WorkController`
  – `celery.worker.Consumer`
  – `celery.worker.request.Request`

  This means that you have to pass a specific app when instantiating these classes.

• `EventDispatcher.copy_buffer` renamed to `app.events.Dispatcher.extend_buffer()`.
• Removed unused and never documented global instance `celery.events.state.state`.
• `app.events.Receiver` is now a `kombu.mixins.ConsumerMixin` subclass.
• `celery.apps.worker.Worker` has been refactored as a subclass of `celery.worker.WorkController`.

  This removes a lot of duplicate functionality.
• The `Celery.with_default_connection` method has been removed in favor of `with app.connection_or_acquire(app.connection_or_acquire())`
• The `celery.results.BaseDictBackend` class has been removed and is replaced by `celery.results.BaseBackend`.

### 3.13.8 Change history

This document contains change notes for bugfix releases in the 3.1.x series (Cipater), please see *What's new in Celery 3.1 (Cipater)* for an overview of what's new in Celery 3.1.

#### 3.1.26

**release-date** 2018-03-23 16:00 PM IST  
**release-by**  Omer Katz  
• Fixed a crash caused by tasks cycling between Celery 3 and Celery 4 workers.

#### 3.1.25

**release-date** 2016-10-10 12:00 PM PDT  
**release-by**  Ask Solem  
• **Requirements**  
  – Now depends on Kombu 3.0.37  
• Fixed problem with chords in group introduced in 3.1.24 (Issue #3504).
3.1.24

release-date  2016-09-30 04:21 PM PDT
release-by  Ask Solem

• Requirements
  – Now depends on Kombu 3.0.36.
  – Now supports Task protocol 2 from the future 4.0 release.
    Workers running 3.1.24 are now able to process messages sent using the new task message protocol to be introduced in Celery 4.0.
    Users upgrading to Celery 4.0 when this is released are encouraged to upgrade to this version as an intermediate step, as this means workers not yet upgraded will be able to process messages from clients/workers running 4.0.
  – Task.send_events can now be set to disable sending of events for that task only.
    Example when defining the task:

    ```python
    @app.task(send_events=False)
    def add(x, y):
        return x + y
    ```

• Utilities: Fixed compatibility with recent psutil versions (Issue #3262).
• Canvas: Chord now forwards partial arguments to its subtasks.
  Fix contributed by Tayfun Sen.
• App: Arguments to app such as backend, broker, etc are now pickled and sent to the child processes on Windows.
  Fix contributed by Jeremy Zafran.
• Deployment: Generic init scripts now supports being symlinked in runlevel directories (Issue #3208).
• Deployment: Updated CentOS scripts to work with CentOS 7.
  Contributed by Joe Sanford.
• Events: The curses monitor no longer crashes when the result of a task is empty.
  Fix contributed by Dongweiming.
• Worker: repr(worker) would crash when called early in the startup process (Issue #2514).
• Tasks: GroupResult now defines __bool__ and __nonzero__.
  This is to fix an issue where a ResultSet or GroupResult with an empty result list are not properly tupled with the as_tuple() method when it is a parent result. This is due to the as_tuple() method performing a logical and operation on the ResultSet.
  Fix contributed by Colin McIntosh.
• Worker: Fixed wrong values in autoscale related logging message.
  Fix contributed by @raducc.
• Documentation improvements by
  – Alexandru Chirila
  – Michael Aquilina
3.1.23

- Programs: Last release broke support for the `--hostname` argument to `celery multi` and `celery worker --detach` (Issue #3103).
- Results: MongoDB result backend could crash the worker at startup if not configured using an URL.

3.1.22

- Programs: The worker would crash immediately on startup on `backend.as_uri()` when using some result backends (Issue #3094).
- Programs: `celery multi/celery worker --detach` would create an extraneous logfile including literal formats (e.g. `%1`) in the filename (Issue #3096).

3.1.21

- Requirements
  - Now depends on Kombu 3.0.34.
  - Now depends on `billiard` 3.3.0.23.
- Prefork pool: Fixes 100% CPU loop on Linux `epoll` (Issue #1845). Also potential fix for: Issue #2142, Issue #2606
- Prefork pool: Fixes memory leak related to processes exiting (Issue #2927).
- Task: An exception is now raised if countdown/expires is less than -2147483648 (Issue #3078).
- Programs: `celery shell --ipython` now compatible with newer IPython versions.
• **Programs:** The DuplicateNodeName warning emitted by inspect/control now includes a list of the node names returned.

  Contributed by Sebastian Kalinowski.

• **Utils:** The `.discard(item)` method of `LimitedSet` didn’t actually remove the item (Issue #3087).

  Fix contributed by Dave Smith.

• **Worker:** Node name formatting now emits less confusing error message for unmatched format keys (Issue #3016).

• **Results:** RPC/AMQP backends: Fixed deserialization of JSON exceptions (Issue #2518).

  Fix contributed by Allard Hoeve.

• **Prefork pool:** The `process inqueue damaged` error message now includes the original exception raised.

• **Documentation:** Includes improvements by:

  – Jeff Widman.

3.1.20

**release-date** 2016-01-22 06:50 p.m. UTC

**release-by** Ask Solem

• **Requirements**

  – Now depends on Kombu 3.0.33.

  – Now depends on billiard 3.3.0.22.

  Includes binary wheels for Microsoft Windows x86 and x86_64!

• **Task:** Error emails now uses utf-8 character set by default (Issue #2737).

• **Task:** Retry now forwards original message headers (Issue #3017).

• **Worker:** Bootsteps can now hook into `on_node_join/leave/lost`.

  See Attributes for an example.

• **Events:** Fixed handling of DST timezones (Issue #2983).

• **Results:** Redis backend stopped respecting certain settings.

  Contributed by Jeremy Llewellyn.

• **Results:** Database backend now properly supports JSON exceptions (Issue #2441).

• **Results:** Redis `new_join` didn’t properly call task errbacks on chord error (Issue #2796).

• **Results:** Restores Redis compatibility with Python `redis < 2.10.0` (Issue #2903).

• **Results:** Fixed rare issue with chord error handling (Issue #2409).

• **Tasks:** Using queue-name values in `CELERY_ROUTES` now works again (Issue #2987).

• **General:** Result backend password now sanitized in report output (Issue #2812, Issue #2004).

• **Configuration:** Now gives helpful error message when the result backend configuration points to a module, and not a class (Issue #2945).

• **Results:** Exceptions sent by JSON serialized workers are now properly handled by pickle configured workers.

• **Programs:** `celery control autoscale` now works (Issue #2950).
• **Programs:** `celery beat --detached` now runs after fork callbacks.

• **General:** Fix for LRU cache implementation on Python 3.5 (Issue #2897).
  
  Contributed by Dennis Brakhane.
  
  Python 3.5’s `OrderedDict` doesn’t allow mutation while it is being iterated over. This breaks “update” if it is called with a dict larger than the maximum size.
  
  This commit changes the code to a version that doesn’t iterate over the dict, and should also be a little bit faster.

• **Init-scripts:** The beat init-script now properly reports service as down when no pid file can be found.
  
  Eric Zarowny

• **Beat:** Added cleaning of corrupted scheduler files for some storage backend errors (Issue #2985).
  
  Fix contributed by Aleksandr Kuznetsov.

• **Beat:** Now syncs the schedule even if the schedule is empty.
  
  Fix contributed by Colin McIntosh.

• **Supervisord:** Set higher process priority in the `supervisord` example.
  
  Contributed by George Tantiras.

• **Documentation:** Includes improvements by:

  ```
  @Bryson Caleb Mingle Christopher Martin Dieter Adriaenssens Jason Veatch Jeremy Cline Juan Rossi Kevin Harvey Kevin McCarthy Kirill Pavlov Marco Buttu @Mayflower Mher Movsisyan Michael Floering @michael-k Nathaniel Varona Rudy Attias Ryan Luckie Steven Parker @squfrans Tadej Janež TakesxiSximada Tom S
  ```

3.1.19

**release-date** 2015-10-26 01:00 p.m. UTC

**release-by** Ask Solem

• **Requirements**
  
  – Now depends on Kombu 3.0.29.
  – Now depends on `billiard` 3.3.0.21.

• **Results:** Fixed MongoDB result backend URL parsing problem (Issue celery/kombu#375).

• **Worker:** Task request now properly sets priority in delivery_info.
  
  Fix contributed by Gerald Manipon.

• **Beat:** PyPy shelve may raise `KeyError` when setting keys (Issue #2862).

• **Programs:** `celery beat --deatched` now working on PyPy.
  
  Fix contributed by Krzysztof Bujniewicz.

• **Results:** Redis result backend now ensures all pipelines are cleaned up.
  
  Contributed by Justin Patrin.

• **Results:** Redis result backend now allows for timeout to be set in the query portion of the result backend URL.
  
  For example `CELERY_RESULT_BACKEND = 'redis://?timeout=10'`
  
  Contributed by Justin Patrin.
• **Results:** result.get now properly handles failures where the exception value is set to None (Issue #2560).
• **Prefork pool:** Fixed attribute error proc.dead.
• **Worker:** Fixed worker hanging when gossip/heartbeat disabled (Issue #1847).
  Fix contributed by Aaron Webber and Bryan Helmig.
• **Results:** MongoDB result backend now supports pymongo 3.x (Issue #2744).
  Fix contributed by Sukrit Khera.
• **Results:** RPC/AMQP backends didn’t deserialize exceptions properly (Issue #2691).
  Fix contributed by Sukrit Khera.
• **Programs:** Fixed problem with celery amqp’s basic_publish (Issue #2013).
• **Worker:** Embedded beat now properly sets app for thread/process (Issue #2594).
• **Documentation:** Many improvements and typos fixed.

Contributions by:

Carlos Garcia-Dubus D. Yu @jerry Jocelyn Delalande Josh Kupershmidt Juan Rossi
@kanemra Paul Pearce Pavel Savchenko Sean Wang Seungha Kim Zhaorong Ma

3.1.18

**release-date** 2015-04-22 05:30 p.m. UTC
**release-by** Ask Solem

• **Requirements**
  – Now depends on Kombu 3.0.25.
  – Now depends on billiard 3.3.0.20.
• **Django:** Now supports Django 1.8 (Issue #2536).
  Fix contributed by Bence Tamas and Mickaël Penhard.
• **Results:** MongoDB result backend now compatible with pymongo 3.0.
  Fix contributed by Fatih Sucu.
• **Tasks:** Fixed bug only happening when a task has multiple callbacks (Issue #2515).
  Fix contributed by NotSqrt.
• **Commands:** Preload options now support --arg value syntax.
  Fix contributed by John Anderson.
• **Compat:** A typo caused celery.log.setup_logging_subsystem to be undefined.
  Fix contributed by Gunnlaugur Thor Briem.
• **init-scripts:** The beat generic init-script now uses /bin/sh instead of bash (Issue #2496).
  Fix contributed by Jelle Verstraatten.
• **Django:** Fixed a TypeError sometimes occurring in logging when validating models.
  Fix contributed by Alexander.
• **Commands:** Worker now supports new --executable argument that can be used with celery worker --detach.
Contributed by Bert Vanderbauwhede.

- **Canvas**: Fixed crash in chord unlock fallback task (Issue #2404).
- **Worker**: Fixed rare crash occurring with `--autoscale` enabled (Issue #2411).
- **Django**: Properly recycle worker Django database connections when the Django `CONN_MAX_AGE` setting is enabled (Issue #2453).
  

### 3.1.17

**release-date**  2014-11-19 03:30 p.m. UTC

**release-by**  Ask Solem

**Don’t enable the CELERYD_FORCE_EXECV setting!**

Please review your configuration and disable this option if you’re using the RabbitMQ or Redis transport.

Keeping this option enabled after 3.1 means the async based prefork pool will be disabled, which can easily cause instability.

- **Requirements**
  
  - Now depends on Kombu 3.0.24.
    
    Includes the new Qpid transport coming in Celery 3.2, backported to support those who may still require Python 2.6 compatibility.
  
  - Now depends on `billiard` 3.3.0.19.
  
  - `celery[librabbitmq]` now depends on `librabbitmq` 1.6.1.

- **Task**: The timing of ETA/countdown tasks were off after the example `LocalTimezone` implementation in the Python documentation no longer works in Python 3.4. (Issue #2306).

- **Task**: Raising `Ignore` no longer sends `task-failed` event (Issue #2365).

- **Redis result backend**: Fixed unbound local errors.

  Fix contributed by Thomas French.

- **Task**: Callbacks wasn’t called properly if `link` was a list of signatures (Issue #2350).

- **Canvas**: chain and group now handles json serialized signatures (Issue #2076).

- **Results**: `.join_native()` would accidentally treat the `STARTED` state as being ready (Issue #2326).
  
  This could lead to the chord callback being called with invalid arguments when using chords with the `CELERY_TRACK_STARTED` setting enabled.

- **Canvas**: The `chord_size` attribute is now set for all canvas primitives, making sure more combinations will work with the `new_join` optimization for Redis (Issue #2339).

- **Task**: Fixed problem with app not being properly propagated to `trace_task` in all cases.

  Fix contributed by @kristaps.

- **Worker**: Expires from task message now associated with a timezone.

  Fix contributed by Albert Wang.

- **Cassandra result backend**: Fixed problems when using detailed mode.
When using the Cassandra backend in detailed mode, a regression caused errors when attempting to retrieve results.

Fix contributed by Gino Ledesma.

- **Mongodb Result backend**: Pickling the backend instance will now include the original URL (Issue #2347).
  
  Fix contributed by Sukrit Khera.

- **Task**: Exception info wasn’t properly set for tasks raising *Reject* (Issue #2043).

- **Worker**: Duplicates are now removed when loading the set of revoked tasks from the worker state database (Issue #2336).

- **celery.contrib.rdb**: Fixed problems with *rdb.set_trace* calling stop from the wrong frame.
  
  Fix contributed by @llllllllll.

- **Canvas**: *chain* and *chord* can now be immutable.

- **Canvas**: *chord.apply_async* will now keep partial args set in *self.args* (Issue #2299).

- **Results**: Small refactoring so that results are decoded the same way in all result backends.

- **Logging**: The *processName* format was introduced in Python 2.6.2 so for compatibility this format is now excluded when using earlier versions (Issue #1644).

### 3.1.16

- **release-date** 2014-10-03 06:00 p.m. UTC

- **release-by** Ask Solem

- **Worker**: 3.1.15 broke *-Ofair* behavior (Issue #2286).
  
  This regression could result in all tasks executing in a single child process if *-Ofair* was enabled.

- **Canvas**: *celery.signature* now properly forwards app argument in all cases.

- **Task**: *retry()* didn’t raise the exception correctly when called without a current exception.
  
  Fix contributed by Andrea Rabbaglietti.

- **Worker**: The *enable_events* remote control command disabled worker-related events by mistake (Issue #2272).
  
  Fix contributed by Konstantinos Koukopoulos.

- **Django**: Adds support for Django 1.7 class names in INSTALLED_APPS when using *app.autodiscover_tasks()* (Issue #2248).

- **Sphinx**: *celery.contrib.sphinx* now uses *getfullargspec* on Python 3 (Issue #2302).

- **Redis/Cache Backends**: Chords will now run at most once if one or more tasks in the chord are executed multiple times for some reason.

### 3.1.15

- **release-date** 2014-09-14 11:00 p.m. UTC

- **release-by** Ask Solem

- **Django**: Now makes sure *django.setup()* is called before importing any task modules (Django 1.7 compatibility, Issue #2227)
• **Results:** `result.get()` was misbehaving by calling `backend.get_task_meta` in a `finally` call leading to AMQP result backend queues not being properly cleaned up (Issue #2245).

3.1.14

**release-date**  2014-09-08 03:00 p.m. UTC

**release-by**  Ask Solem

**Requirements**

– Now depends on Kombu 3.0.22.

**Init-scripts:** The generic worker init-scripts `status` command now gets an accurate pidfile list (Issue #1942).

**Init-scripts:** The generic beat script now implements the `status` command.

  Contributed by John Whitlock.

**Commands:** Multi now writes informational output to stdout instead of stderr.

**Worker:** Now ignores not implemented error for `pool.restart` (Issue #2153).

**Task:** Retry no longer raises retry exception when executed in eager mode (Issue #2164).

**AMQP Result backend:** Now ensured `on_interval` is called at least every second for blocking calls to properly propagate parent errors.

**Django:** Compatibility with Django 1.7 on Windows (Issue #2126).

**Programs:** `--umask` argument can now be specified in both octal (if starting with 0) or decimal.

3.1.13

**Security Fixes**

• [Security: CELERYSA-0002] Insecure default umask.

  The built-in utility used to daemonize the Celery worker service sets an insecure umask by default (umask 0).

  This means that any files or directories created by the worker will end up having world-writable permissions.

  Special thanks to Red Hat for originally discovering and reporting the issue!

  This version will no longer set a default umask by default, so if unset the umask of the parent process will be used.

**News**

• **Requirements**

  – Now depends on Kombu 3.0.21.

  – Now depends on billiard 3.3.0.18.

• **App:** backend argument now also sets the `CELERY_RESULT_BACKEND` setting.

• **Task:** `signature_from_request` now propagates reply_to so that the RPC backend works with retried tasks (Issue #2113).
• **Task**: retry will no longer attempt to re-queue the task if sending the retry message fails.
  
  Unrelated exceptions being raised could cause a message loop, so it was better to remove this behavior.

• **Beat**: Accounts for standard 1ms drift by always waking up 0.010s earlier.
  
  This will adjust the latency so that the periodic tasks won’t move 1ms after every invocation.

• Documentation fixes
  
  Contributed by Yuval Greenfield, Lucas Wiman, @nicholsonfj.

• **Worker**: Removed an outdated assert statement that could lead to errors being masked (Issue #2086).

### 3.1.12

**release-date** 2014-06-09 10:12 p.m. UTC

**release-by** Ask Solem

• **Requirements**
  
  Now depends on Kombu 3.0.19.

• **App**: Connections weren’t being closed after fork due to an error in the after fork handler (Issue #2055).
  
  This could manifest itself by causing framing errors when using RabbitMQ. (Unexpected frame).

• **Django**: django.setup() was being called too late when using Django 1.7 (Issue #1802).

• **Django**: Fixed problems with event timezones when using Django (Substantial drift).
  
  Celery didn’t take into account that Django modifies the time.timezone attributes and friends.

• **Canvas**: Signature.link now works when the link option is a scalar value (Issue #2019).

• **Prefork pool**: Fixed race conditions for when file descriptors are removed from the event loop.
  
  Fix contributed by Roger Hu.

• **Prefork pool**: Improved solution for dividing tasks between child processes.
  
  This change should improve performance when there are many child processes, and also decrease the chance that two subsequent tasks are written to the same child process.

• **Worker**: Now ignores unknown event types, instead of crashing.
  
  Fix contributed by Illes Solt.

• **Programs**: celery worker --detach no longer closes open file descriptors when C_FAKEFORK is used so that the workers output can be seen.

• **Programs**: The default working directory for celery worker --detach is now the current working directory, not /.

• **Canvas**: signature(s, app=app) didn’t upgrade serialized signatures to their original class (subtask_type) when the app keyword argument was used.

• **Control**: The duplicate nodename warning emitted by control commands now shows the duplicate node name.

• **Tasks**: Can now call ResultSet.get() on a result set without members.
  
  Fix contributed by Alexey Kotlyarov.
• **App:** Fixed strange traceback mangling issue for `app.connection_or_acquire`.

• **Programs:** The `celery multi stopwait` command is now documented in usage.

• **Other:** Fixed cleanup problem with `PromiseProxy` when an error is raised while trying to evaluate the promise.

• **Other:** The utility used to censor configuration values now handles non-string keys.

• **Other:** The `inspect conf` command didn’t handle non-string keys well.
  Fix contributed by Jay Farrimond.

• **Programs:** Fixed argument handling problem in `celery worker --detach`.
  Fix contributed by Dmitry Malinovsky.

• **Programs:** `celery worker --detach` didn’t forward working directory option (Issue #2003).

• **Programs:** `celery inspect registered` no longer includes the list of built-in tasks.

• **Worker:** The `requires` attribute for boot steps weren’t being handled correctly (Issue #2002).

• **Eventlet:** The eventlet pool now supports the `pool_grow` and `pool_shrink` remote control commands.
  Contributed by Mher Movsisyan.

• **Eventlet:** The eventlet pool now implements statistics for `:program:celery inspect stats`.
  Contributed by Mher Movsisyan.

• **Documentation:** Clarified `Task.rate_limit` behavior.
  Contributed by Jonas Haag.

• **Documentation:** `AbortableTask` examples now updated to use the new API (Issue #1993).

• **Documentation:** The security documentation examples used an out of date import.
  Fix contributed by Ian Dees.

• **Init-scripts:** The CentOS init-scripts didn’t quote `CELERY_CHDIR`.
  Fix contributed by @ffeast.

### 3.1.11

**release-date** 2014-04-16 11:00 p.m. UTC

**release-by** Ask Solem

• **Now compatible with RabbitMQ 3.3.0**

  You need to run Celery 3.1.11 or later when using RabbitMQ 3.3, and if you use the `librabbitmq` module you also have to upgrade to `librabbitmq 1.5.0`:

  ```
  $ pip install -U librabbitmq
  ```

• **Requirements:**
  
  – Now depends on Kombu 3.0.15.
  – Now depends on `billiard 3.3.0.17`.
  – Bundle `celery[librabbitmq]` now depends on `librabbitmq 1.5.0`. 
• **Tasks:** The `CELERY_DEFAULT_DELIVERY_MODE` setting was being ignored (Issue #1953).

• **Worker:** New `celery worker --heartbeat-interval` can be used to change the time (in seconds) between sending event heartbeats.

  Contributed by Matthew Duggan and Craig Northway.

• **App:** Fixed memory leaks occurring when creating lots of temporary app instances (Issue #1949).

• **MongoDB:** SSL configuration with non-MongoDB transport breaks MongoDB results backend (Issue #1973).

  Fix contributed by Brian Bouterse.

• **Logging:** The color formatter accidentally modified `record.msg` (Issue #1939).

• **Results:** Fixed problem with task trails being stored multiple times, causing `result.collect()` to hang (Issue #1936, Issue #1943).

• **Results:** `ResultSet` now implements a `.backend` attribute for compatibility with `AsyncResult`.

• **Results:** `.forget()` now also clears the local cache.

• **Results:** Fixed problem with multiple calls to `result._set_cache` (Issue #1940).

• **Results:** `join_native` populated result cache even if disabled.

• **Results:** The YAML result serializer should now be able to handle storing exceptions.

• **Worker:** No longer sends task error emails for expected errors (in `@task(throws=(..., ))`).

• **Canvas:** Fixed problem with exception deserialization when using the JSON serializer (Issue #1987).

• **Eventlet:** Fixes crash when `celery.contrib.batches` attempted to cancel a non-existing timer (Issue #1984).

• Can now import `celery.version_info_t`, and `celery.five` (Issue #1968).

### 3.1.10

**release-date** 2014-03-22 09:40 p.m. UTC

**release-by** Ask Solem

• **Requirements:**
  – Now depends on Kombu 3.0.14.

• **Results:**

  Reliability improvements to the SQLAlchemy database backend. Previously the connection from the MainProcess was improperly shared with the workers. (Issue #1786)

• **Redis:** Important note about events (Issue #1882).

  There’s a new transport option for Redis that enables monitors to filter out unwanted events. Enabling this option in the workers will increase performance considerably:

  ```
  BROKER_TRANSPORT_OPTIONS = {'fanout_patterns': True}
  ```

  Enabling this option means that your workers won’t be able to see workers with the option disabled (or is running an older version of Celery), so if you do enable it then make sure you do so on all nodes.

  See **Caveats**.

  This will be the default in Celery 3.2.
• **Results:** The `app.AsyncResult` object now keeps a local cache of the final state of the task.

This means that the global result cache can finally be disabled, and you can do so by setting `CELERY_MAX_CACHED_RESULTS` to `-1`. The lifetime of the cache will then be bound to the lifetime of the result object, which will be the default behavior in Celery 3.2.

• **Events:** The “Substantial drift” warning message is now logged once per node name only (Issue #1802).

• **Worker:** Ability to use one log file per child process when using the prefork pool.

This can be enabled by using the new `%i` and `%I` format specifiers for the log file name. See *Prefork pool process index*.

• **Redis:** New experimental chord join implementation.

This is an optimization for chords when using the Redis result backend, where the join operation is now considerably faster and using less resources than the previous strategy.

The new option can be set in the result backend URL:

```python
CELERY_RESULT_BACKEND = 'redis://localhost?new_join=1'
```

This must be enabled manually as it’s incompatible with workers and clients not using it, so be sure to enable the option in all clients and workers if you decide to use it.

• **Multi:** With `-opt:index` (e.g., `-c:1`) the index now always refers to the position of a node in the argument list.

This means that referring to a number will work when specifying a list of node names and not just for a number range:

```
celery multi start A B C D -c:1 4 -c:2-4 8
```

In this example 1 refers to node A (as it’s the first node in the list).

• **Signals:** The sender argument to `Signal.connect` can now be a proxy object, which means that it can be used with the task decorator (Issue #1873).

• **Task:** A regression caused the `queue` argument to `Task.retry` to be ignored (Issue #1892).

• **App:** Fixed error message for `config_from_envvar()`.

  Fix contributed by Dmitry Malinovsky.

• **Canvas:** Chords can now contain a group of other chords (Issue #1921).

• **Canvas:** Chords can now be combined when using the amqp result backend (a chord where the callback is also a chord).

• **Canvas:** Calling `result.get()` for a chain task will now complete even if one of the tasks in the chain is `ignore_result=True` (Issue #1905).

• **Canvas:** Worker now also logs chord errors.

• **Canvas:** A chord task raising an exception will now result in any errbacks (`link_error`) to the chord callback to also be called.

• **Results:** Reliability improvements to the SQLAlchemy database backend (Issue #1786).

  Previously the connection from the `MainProcess` was improperly inherited by child processes.

  Fix contributed by Ionel Cristian Măries.

• **Task:** Task callbacks and errbacks are now called using the group primitive.

• **Task:** `Task.apply` now properly sets `request.headers` (Issue #1874).
• **Worker:** Fixed `UnicodeEncodeError` occurring when worker is started by `supervisor`.
  Fix contributed by Codeb Fan.

• **Beat:** No longer attempts to upgrade a newly created database file (Issue #1923).

• **Beat:** New setting `CELERYBEAT_SYNC_EVERY` can be used to control file sync by specifying the number of tasks to send between each sync.
  Contributed by Chris Clark.

• **Commands:** `celery inspect memdump` no longer crashes if the `psutil` module isn’t installed (Issue #1914).

• **Worker:** Remote control commands now always accepts json serialized messages (Issue #1870).

• **Worker:** Gossip will now drop any task related events it receives by mistake (Issue #1882).

### 3.1.9

**release-date** 2014-02-10 06:43 p.m. UTC

**release-by** Ask Solem

• **Requirements:**
  – Now depends on Kombu 3.0.12.

• **Prefork pool:** Better handling of exiting child processes.
  Fix contributed by Ionel Cristian Măries.

• **Prefork pool:** Now makes sure all file descriptors are removed from the hub when a process is cleaned up.
  Fix contributed by Ionel Cristian Măries.

• **New Sphinx extension:** for autodoc documentation of tasks: `celery.contrib.spinx` (Issue #1833).

• **Django:** Now works with Django 1.7a1.

• **Task:** `Task.backend` is now a property that forwards to `app.backend` if no custom backend has been specified for the task (Issue #1821).

• **Generic init-scripts:** Fixed bug in stop command.
  Fix contributed by Rinat Shigapov.

• **Generic init-scripts:** Fixed compatibility with GNU `stat`.
  Fix contributed by Paul Kilgo.

• **Generic init-scripts:** Fixed compatibility with the minimal `dash` shell (Issue #1815).

• **Commands:** The `celery amqp basic.publish` command wasn’t working properly.
  Fix contributed by Andrey Voronov.

• **Commands:** Did no longer emit an error message if the pidfile exists and the process is still alive (Issue #1855).

• **Commands:** Better error message for missing arguments to preload options (Issue #1860).

• **Commands:** `celery -h` didn’t work because of a bug in the argument parser (Issue #1849).

• **Worker:** Improved error message for message decoding errors.

• **Time:** Now properly parses the Z timezone specifier in ISO 8601 date strings.
  Fix contributed by Martin Davidsson.
• **Worker**: Now uses the *negotiated* heartbeat value to calculate how often to run the heartbeat checks.

• **Beat**: Fixed problem with beat hanging after the first schedule iteration (Issue #1822).
  
  Fix contributed by Roger Hu.

• **Signals**: The header argument to `before_task_publish` is now always a dictionary instance so that signal handlers can add headers.

• **Worker**: A list of message headers is now included in message related errors.

### 3.1.8

**release-date**  2014-01-17 10:45 p.m. UTC

**release-by**  Ask Solem

**Requirements**:

– Now depends on Kombu 3.0.10.

– Now depends on billiard 3.3.0.14.

**Worker**: The event loop wasn’t properly reinitialized at consumer restart which would force the worker to continue with a closed `epoll` instance on Linux, resulting in a crash.

**Events**: Fixed issue with both heartbeats and task events that could result in the data not being kept in sorted order.

  As a result this would force the worker to log “heartbeat missed” events even though the remote node was sending heartbeats in a timely manner.

**Results**: The pickle serializer no longer converts group results to tuples, and will keep the original type (Issue #1750).

**Results**: `ResultSet.iterate` is now pending deprecation.

  The method will be deprecated in version 3.2 and removed in version 3.3.

  Use `result.get(callback=)` (or `result.iter_native()` where available) instead.

**Worker** `eventlet/gevent`: A regression caused `Control-c` to be ineffective for shutdown.

**Redis result backend**: Now using a pipeline to store state changes for improved performance.

  Contributed by Pepijn de Vos.

**Redis result backend**: Will now retry storing the result if disconnected.

**Worker** `gossip`: Fixed attribute error occurring when another node leaves.

  Fix contributed by Brodie Rao.

**Generic init-scripts**: Now runs a check at start-up to verify that any configuration scripts are owned by root and that they aren’t world/group writable.

  The init-script configuration is a shell script executed by root, so this is a preventive measure to ensure that users don’t leave this file vulnerable to changes by unprivileged users.

**Note**: Note that upgrading Celery won’t update the init-scripts, instead you need to manually copy the improved versions from the source distribution: [https://github.com/celery/celery/tree/3.1/extra/generic-init.d](https://github.com/celery/celery/tree/3.1/extra/generic-init.d)
• **Commands**: The `celery purge` command now warns that the operation will delete all tasks and prompts the user for confirmation.

  A new `-f` was added that can be used to disable interactive mode.

• **Task**: `.retry()` didn’t raise the value provided in the `exc` argument when called outside of an error context *(Issue #1755)*.

• **Commands**: The `celery multi` command didn’t forward command line configuration to the target workers.

  The change means that multi will forward the special `--` argument and configuration content at the end of the arguments line to the specified workers.

  Example using command-line configuration to set a broker heartbeat from `celery multi`:

  ```bash
  $ celery multi start 1 -c3 -- broker.heartbeat=30
  ```

  Fix contributed by Antoine Legrand.

• **Canvas**: `chain.apply_async()` now properly forwards execution options.

  Fix contributed by Konstantin Podshumok.

• **Redis result backend**: Now takes `connection_pool` argument that can be used to change the connection pool class/constructor.

• **Worker**: Now truncates very long arguments and keyword arguments logged by the pool at debug severity.

• **Worker**: The worker now closes all open files on `SIGHUP` (regression) *(Issue #1768)*.

  Fix contributed by Brodie Rao

• **Worker**: Will no longer accept remote control commands while the worker start-up phase is incomplete *(Issue #1741)*.

• **Commands**: The output of the event dump utility (`celery events -d`) can now be piped into other commands.

• **Documentation**: The RabbitMQ installation instructions for macOS was updated to use modern Homebrew practices.

  Contributed by Jon Chen.

• **Commands**: The `celery inspect conf` utility now works.

• **Commands**: The `--no-color` argument was not respected by all commands *(Issue #1799)*.

• **App**: Fixed rare bug with `autodiscover_tasks()` *(Issue #1797)*.

• **Distribution**: The sphinx docs will now always add the parent directory to path so that the current Celery source code is used as a basis for API documentation *(Issue #1782)*.

• **Documentation**: `supervisor` examples contained an extraneous ‘-’ in a `--logfile` argument example.

  Fix contributed by Mohammad Almeer.

### 3.1.7

**release-date** 2013-12-17 06:00 p.m. UTC

**release-by** Ask Solem
Important Notes

Init-script security improvements

Where the generic init-scripts (for `celeryd` and `celerybeat`) before delegated the responsibility of dropping privileges to the target application, it will now use `su` instead, so that the Python program isn’t trusted with superuser privileges.

This isn’t in reaction to any known exploit, but it will limit the possibility of a privilege escalation bug being abused in the future.

You have to upgrade the init-scripts manually from this directory: https://github.com/celery/celery/tree/3.1/extra/generic-init.d

AMQP result backend

The 3.1 release accidentally left the amqp backend configured to be non-persistent by default.

Upgrading from 3.0 would give a “not equivalent” error when attempting to set or retrieve results for a task. That’s unless you manually set the persistence setting:

```
CELERY_RESULT_PERSISTENT = True
```

This version restores the previous value so if you already forced the upgrade by removing the existing exchange you must either keep the configuration by setting `CELERY_RESULT_PERSISTENT = False` or delete the `celeryresults` exchange again.

Synchronous subtasks

Tasks waiting for the result of a subtask will now emit a `RuntimeWarning` warning when using the prefork pool, and in 3.2 this will result in an exception being raised.

It’s not legal for tasks to block by waiting for subtasks as this is likely to lead to resource starvation and eventually deadlock when using the prefork pool (see also Avoid launching synchronous subtasks).

If you really know what you’re doing you can avoid the warning (and the future exception being raised) by moving the operation in a white-list block:

```
from celery.result import allow_join_result

@app.task
def misbehaving():
    result = other_task.delay()
    with allow_join_result():
        result.get()
```

Note also that if you wait for the result of a subtask in any form when using the prefork pool you must also disable the pool prefetching behavior with the worker `-Ofair` option.

Fixes

- Now depends on Kombu 3.0.8.
- Now depends on `billiard` 3.3.0.13
• Events: Fixed compatibility with non-standard json libraries that sends float as `decimal.Decimal` (Issue #1731)

• Events: State worker objects now always defines attributes: `active`, `processed`, `loadavg`, `sw_ident`, `sw_ver` and `sw_sys`.

• Worker: Now keeps count of the total number of tasks processed, not just by type (all_active_count).

• Init-scripts: Fixed problem with reading configuration file when the init-script is symlinked to a runlevel (e.g., S02celeryd). (Issue #1740).

  This also removed a rarely used feature where you can symlink the script to provide alternative configurations. You instead copy the script and give it a new name, but perhaps a better solution is to provide arguments to `CELDYD_OPTS` to separate them:

  ```
  CELERYD_NODES="X1 X2 Y1 Y2"
  CELERYD_OPTS="-A:X1 x -A:X2 x -A:Y1 y -A:Y2 y"
  ```

• Fallback chord unlock task is now always called after the chord header (Issue #1700).

  This means that the unlock task won’t be started if there’s an error sending the header.

• Celery command: Fixed problem with arguments for some control commands.

  Fix contributed by Konstantin Podshumok.

• Fixed bug in `utcoffset` where the offset when in DST would be completely wrong (Issue #1743).

• Worker: Errors occurring while attempting to serialize the result of a task will now cause the task to be marked with failure and a `kombu.exceptions.EncodingError` error.

  Fix contributed by Ionel Cristian Mărășe

• Worker with `-B` argument didn’t properly shut down the beat instance.

• Worker: The `%n` and `%h` formats are now also supported by the `--logfile`, `--pidfile` and `--statedb` arguments.

  Example:

  ```
  $ celery -A proj worker -n foo@%h --logfile=%n.log --statedb=%n.db
  ```

• Redis/Cache result backends: Will now timeout if keys evicted while trying to join a chord.

• The fallback unlock chord task now raises `Retry` so that the retry even is properly logged by the worker.

• Multi: Will no longer apply Eventlet/gevent monkey patches (Issue #1717).

• Redis result backend: Now supports UNIX sockets.

  Like the Redis broker transport the result backend now also supports using `redis+socket`:// `tmp/redis.sock` URLs.

  Contributed by Alcides Viamontes Esquivel.

• Events: Events sent by clients was mistaken for worker related events (Issue #1714).

  For `events.State` the tasks now have a `Task.client` attribute that’s set when a `task-sent` event is being received.

  Also, a clients logical clock isn’t in sync with the cluster so they live in a “time bubble.” So for this reason monitors will no longer attempt to merge with the clock of an event sent by a client, instead it will fake the value by using the current clock with a skew of -1.

• Prefork pool: The method used to find terminated processes was flawed in that it didn’t also take into account missing `popen` objects.
• Canvas: group and chord now works with anon signatures as long as the group/chord object is associated with an app instance (Issue #1744).

You can pass the app by using `group(..., app=app)`.

### 3.1.6

**release-date** 2013-12-02 06:00 p.m. UTC

**release-by** Ask Solem

• Now depends on billiard 3.3.0.10.

• Now depends on Kombu 3.0.7.

• Fixed problem where Mingle caused the worker to hang at start-up (Issue #1686).

• Beat: Would attempt to drop privileges twice (Issue #1708).

• Windows: Fixed error with `geteuid` not being available (Issue #1676).

• Tasks can now provide a list of expected error classes (Issue #1682).

The list should only include errors that the task is expected to raise during normal operation:

```python
@task(throws=(KeyError, HttpNotFound))
```

What happens when an exception is raised depends on the type of error:

– Expected errors (included in `Task.throws`)
  
  Will be logged using severity `INFO`, and traceback is excluded.

– Unexpected errors

  Will be logged using severity `ERROR`, with traceback included.

• Cache result backend now compatible with Python 3 (Issue #1697).

• CentOS init-script: Now compatible with SysV style init symlinks.

  Fix contributed by Jonathan Jordan.

• Events: Fixed problem when task name isn’t defined (Issue #1710).

  Fix contributed by Mher Movsisyan.

• Task: Fixed unbound local errors (Issue #1684).

  Fix contributed by Markus Ullmann.

• Canvas: Now unrolls groups with only one task (optimization) (Issue #1656).

• Task: Fixed problem with ETA and timezones.

  Fix contributed by Alexander Koval.

• Django: Worker now performs model validation (Issue #1681).

• Task decorator now emits less confusing errors when used with incorrect arguments (Issue #1692).

• Task: New method `Task.send_event` can be used to send custom events to Flower and other monitors.

• Fixed a compatibility issue with non-abstract task classes

• Events from clients now uses new node name format (`gen<pid>@<hostname>`).

• Fixed rare bug with Callable not being defined at interpreter shutdown (Issue #1678).
Fix contributed by Nick Johnson.

• Fixed Python 2.6 compatibility (Issue #1679).

3.1.5

**release-date** 2013-11-21 06:20 p.m. UTC

**release-by** Ask Solem

• Now depends on Kombu 3.0.6.
• Now depends on billiard 3.3.0.8
• App: `config_from_object` is now lazy (Issue #1665).
• App: `autodiscover_tasks` is now lazy.

  Django users should now wrap access to the settings object in a lambda:

  ```python
  app.autodiscover_tasks(lambda: settings.INSTALLED_APPS)
  ```

  this ensures that the settings object isn’t prepared prematurely.

• Fixed regression for `--app` argument experienced by some users (Issue #1653).
• Worker: Now respects the `--uid` and `--gid` arguments even if `--detach` isn’t enabled.
• Beat: Now respects the `--uid` and `--gid` arguments even if `--detach` isn’t enabled.
• Python 3: Fixed unorderable error occurring with the worker `-B` argument enabled.
• `celery.VERSION` is now a named tuple.
• `maybe_signature(list)` is now applied recursively (Issue #1645).
• `celery shell` command: Fixed `IPython.frontend` deprecation warning.
• The default app no longer includes the built-in fix-ups.

  This fixes a bug where `celery multi` would attempt to load the Django settings module before entering the target working directory.

• The Django daemonization tutorial was changed.

  Users no longer have to explicitly export `DJANGO_SETTINGS_MODULE` in `/etc/default/celeryd` when the new project layout is used.
• Redis result backend: expiry value can now be 0 (Issue #1661).
• Censoring settings now accounts for non-string keys (Issue #1663).
• App: New `autofinalize` option.

  Apps are automatically finalized when the task registry is accessed. You can now disable this behavior so that an exception is raised instead.

  Example:

  ```python
  app = Celery(autofinalize=False)
  # raises RuntimeError
  tasks = app.tasks
  @app.task
  ```

(continues on next page)
```python
def add(x, y):
    return x + y

# raises RuntimeError
add.delay(2, 2)

app.finalize()
# no longer raises:
tasks = app.tasks
add.delay(2, 2)
```

- The worker didn’t send monitoring events during shutdown.
- Worker: Mingle and gossip is now automatically disabled when used with an unsupported transport (Issue #1664).
- `celery` command: Preload options now supports the rare `--opt` value format (Issue #1668).
- `celery` command: Accidentally removed options appearing before the sub-command, these are now moved to the end instead.
- Worker now properly responds to `inspect stats` commands even if received before start-up is complete (Issue #1659).
- `task_postrun` is now sent within a `finally` block, to make sure the signal is always sent.
- Beat: Fixed syntax error in string formatting.
  Contributed by @nadad.
- Fixed typos in the documentation.
  Fixes contributed by Loic Bistuer, @sunfinite.
- Nested chains now works properly when constructed using the `chain` type instead of the `|` operator (Issue #1656).

### 3.1.4

**release-date** 2013-11-15 11:40 p.m. UTC

**release-by** Ask Solem

- Now depends on Kombu 3.0.5.
- Now depends on `billiard 3.3.0.7`
- Worker accidentally set a default socket timeout of 5 seconds.
- Django: Fix-up now sets the default app so that threads will use the same app instance (e.g., for `manage.py runserver`).
- Worker: Fixed Unicode error crash at start-up experienced by some users.
- Calling `.apply_async` on an empty chain now works again (Issue #1650).
- The `celery multi show` command now generates the same arguments as the start command does.
- The `--app` argument could end up using a module object instead of an app instance (with a resulting crash).
- Fixed a syntax error problem in the beat init-script.
  Fix contributed by Vsevolod.
• Tests now passing on PyPy 2.1 and 2.2.

3.1.3

**release-date** 2013-11-13 00:55 a.m. UTC  
**release-by** Ask Solem   
• Fixed compatibility problem with Python 2.7.0 - 2.7.5 (Issue #1637)   
  unpack_from started supporting memoryview arguments in Python 2.7.6.   
• Worker: -S argument accidentally closed files used for logging.   
• Task decorated tasks now keep their docstring (Issue #1636)

3.1.2

**release-date** 2013-11-12 08:00 p.m. UTC  
**release-by** Ask Solem   
• Now depends on billiard 3.3.0.6   
• No longer needs the billiard C extension to be installed.   
• The worker silently ignored task errors.   
• Django: Fixed ImproperlyConfigured error raised when no database backend specified.   
  Fix contributed by @j0hnsmith.   
• Prefork pool: Now using _multiprocessing.read with memoryview if available.   
• close_open_fds now uses os.closerange if available.   
• get_fdmax now takes value from sysconfig if possible.

3.1.1

**release-date** 2013-11-11 06:30 p.m. UTC  
**release-by** Ask Solem   
• Now depends on billiard 3.3.0.4.   
• Python 3: Fixed compatibility issues.   
• Windows: Accidentally showed warning that the billiard C extension wasn’t installed (Issue #1630).   
• Django: Tutorial updated with a solution that sets a default DJANGO_SETTINGS_MODULE so that it doesn’t have to be typed in with the celery command.   
  Also fixed typos in the tutorial, and added the settings required to use the Django database backend.   
  Thanks to Chris Ward, @orarbel.   
• Django: Fixed a problem when using the Django settings in Django 1.6.   
• Django: Fix-up shouldn’t be applied if the django loader is active.   
• Worker: Fixed attribute error for human_write_stats when using the compatibility prefork pool implementation.
• Worker: Fixed compatibility with billiard without C extension.
• Inspect.conf: Now supports a with_defaults argument.
• Group.restore: The backend argument wasn’t respected.

3.1.0

release-date  2013-11-09 11:00 p.m. UTC
release-by   Ask Solem

See What’s new in Celery 3.1 (Cipater).

3.13.9 What’s new in Celery 3.0 (Chiastic Slide)

Celery is a simple, flexible, and reliable distributed system to process vast amounts of messages, while providing operations with the tools required to maintain such a system.

It’s a task queue with focus on real-time processing, while also supporting task scheduling.

Celery has a large and diverse community of users and contributors, you should come join us on IRC or our mailing-list.

To read more about Celery you should go read the introduction.

While this version is backward compatible with previous versions it’s important that you read the following section.

If you use Celery in combination with Django you must also read the django-celery changelog and upgrade to django-celery 3.0.

This version is officially supported on CPython 2.5, 2.6, 2.7, 3.2 and 3.3, as well as PyPy and Jython.

Highlights

Overview

• A new and improved API, that’s both simpler and more powerful.
  Everyone must read the new First Steps with Celery tutorial, and the new Next Steps tutorial. Oh, and why not reread the user guide while you’re at it :)
  There are no current plans to deprecate the old API, so you don’t have to be in a hurry to port your applications.
• The worker is now thread-less, giving great performance improvements.
• The new “Canvas” makes it easy to define complex work-flows.
  Ever wanted to chain tasks together? This is possible, but not just that, now you can even chain together groups and chords, or even combine multiple chains.
  Read more in the Canvas user guide.
• All of Celery’s command-line programs are now available from a single celery umbrella command.
• This is the last version to support Python 2.5.
  Starting with Celery 3.1, Python 2.6 or later is required.
• Support for the new librabbitmq C client.

Celery will automatically use the librabbitmq module if installed, which is a very fast and memory-optimized replacement for the amqp module.

• Redis support is more reliable with improved ack emulation.
• Celery now always uses UTC
• Over 600 commits, 30k additions/36k deletions.

In comparison 1.0 2.0 had 18k additions/8k deletions.

**Important Notes**

**Broadcast exchanges renamed**

The workers remote control command exchanges has been renamed (a new pidbox name), this is because the auto_delete flag on the exchanges has been removed, and that makes it incompatible with earlier versions.

You can manually delete the old exchanges if you want, using the celery amqp command (previously called camqadm):

```
$ celery amqp exchange.delete celeryd.pidbox
$ celery amqp exchange.delete reply.celeryd.pidbox
```

**Event-loop**

The worker is now running without threads when used with RabbitMQ (AMQP), or Redis as a broker, resulting in:

• Much better overall performance.
• Fixes several edge case race conditions.
• Sub-millisecond timer precision.
• Faster shutdown times.

The transports supported are: py-amqplibrabbitmq, redis, and amqplib. Hopefully this can be extended to include additional broker transports in the future.

For increased reliability the CELERY_FORCE_EXECV setting is enabled by default if the event-loop isn’t used.

**New celery umbrella command**

All Celery’s command-line programs are now available from a single celery umbrella command.

You can see a list of sub-commands and options by running:

```
$ celery help
```

Commands include:

• celery worker (previously celeryd).
• celery beat (previously celerybeat).
• celery amqp (previously camqadm).
The old programs are still available (celeryd, celerybeat, etc), but you’re discouraged from using them.

Now depends on billiard

Billiard is a fork of the multiprocessing containing the no-execv patch by sbt (http://bugs.python.org/issue8713), and also contains the pool improvements previously located in Celery.

This fork was necessary as changes to the C extension code was required for the no-execv patch to work.

- Issue #625
- Issue #627
- Issue #640
- django-celery #122 <https://github.com/celery/django-celery/issues/122>
- django-celery #124 <https://github.com/celery/django-celery/issues/122>

celery.app.task no longer a package

The celery.app.task module is now a module instead of a package.

The setup.py install script will try to remove the old package, but if that doesn’t work for some reason you have to remove it manually. This command helps:

```
$ rm -r $(dirname $(python -c 'import celery;print(celery.__file__)'))/app/task/
```

If you experience an error like `ImportError: cannot import name _unpickle_task, you just have to remove the old package and everything is fine.

Last version to support Python 2.5

The 3.0 series will be last version to support Python 2.5, and starting from 3.1 Python 2.6 and later will be required.

With several other distributions taking the step to discontinue Python 2.5 support, we feel that it is time too.

Python 2.6 should be widely available at this point, and we urge you to upgrade, but if that’s not possible you still have the option to continue using the Celery 3.0, and important bug fixes introduced in Celery 3.1 will be back-ported to Celery 3.0 upon request.

UTC timezone is now used

This means that ETA/countdown in messages aren’t compatible with Celery versions prior to 2.5.

You can disable UTC and revert back to old local time by setting the CELERY_ENABLE_UTC setting.

Redis: Ack emulation improvements

Reducing the possibility of data loss.

Acks are now implemented by storing a copy of the message when the message is consumed. The copy isn’t removed until the consumer acknowledges or rejects it.

This means that unacknowledged messages will be redelivered either when the connection is closed, or when the visibility timeout is exceeded.
• Visibility timeout

This is a timeout for acks, so that if the consumer doesn’t ack the message within this time limit, the message is redelivered to another consumer.

The timeout is set to one hour by default, but can be changed by configuring a transport option:

```python
BROKER_TRANSPORT_OPTIONS = {'visibility_timeout': 18000} # 5 hours
```

**Note:** Messages that haven’t been acked will be redelivered if the visibility timeout is exceeded, for Celery users this means that ETA/countdown tasks that are scheduled to execute with a time that exceeds the visibility timeout will be executed twice (or more). If you plan on using long ETA/countdowns you should tweak the visibility timeout accordingly.

Setting a long timeout means that it’ll take a long time for messages to be redelivered in the event of a power failure, but if so happens you could temporarily set the visibility timeout lower to flush out messages when you start up the systems again.

**News**

**Chaining Tasks**

Tasks can now have callbacks and errbacks, and dependencies are recorded

• The task message format have been updated with two new extension keys

  Both keys can be empty/undefined or a list of subtasks.

  - **callbacks**
    
    Applied if the task exits successfully, with the result of the task as an argument.

  - **errbacks**
    
    Applied if an error occurred while executing the task, with the uuid of the task as an argument. Since it may not be possible to serialize the exception instance, it passes the uuid of the task instead. The uuid can then be used to retrieve the exception and traceback of the task from the result backend.

  - **link** and **link_error** keyword arguments has been added to `apply_async`.

    These add callbacks and errbacks to the task, and you can read more about them at [Linking (callbacks/errbacks)].

  - We now track what subtasks a task sends, and some result backends supports retrieving this information.

    * **task.request.children**
      
      Contains the result instances of the subtasks the currently executing task has applied.

    * **AsyncResult.children**
      
      Returns the tasks dependencies, as a list of `AsyncResult/ResultSet` instances.

    * **AsyncResult.iterdeps**
Recursively iterates over the tasks dependencies, yielding `(parent, node)` tuples.

Raises IncompleteStream if any of the dependencies hasn’t returned yet.

* `AsyncResult.graph`

A `DependencyGraph` of the tasks dependencies. With this you can also convert to dot format:

```python
with open('graph.dot') as fh:
    result.graph.to_dot(fh)
```

then produce an image of the graph:

```bash
$ dot -Tpng graph.dot -o graph.png
```

• A new special subtask called `chain` is also included:

```python
>>> from celery import chain

# (2 + 2) * 8 / 2
>>> res = chain(add.subtask((2, 2)),
              mul.subtask((8,)),
              div.subtask((2,))).apply_async()
```

```python
>>> res.get() == 16
>>> res.parent.get() == 32
>>> res.parent.parent.get() == 4
```

* Adds `AsyncResult.get_leaf()`

Waits and returns the result of the leaf subtask. That’s the last node found when traversing the graph, but this means that the graph can be 1-dimensional only (in effect a list).

* Adds `subtask.link(subtask) + subtask.link_error(subtask)`

Shortcut to `s.options.setdefault('link', []).append(subtask)`

* Adds `subtask.flatten_links()`

Returns a flattened list of all dependencies (recursively)

**Redis: Priority support**

The message’s `priority` field is now respected by the Redis transport by having multiple lists for each named queue. The queues are then consumed by in order of priority.

The priority field is a number in the range of 0 - 9, where 0 is the default and highest priority.

The priority range is collapsed into four steps by default, since it is unlikely that nine steps will yield more benefit than using four steps. The number of steps can be configured by setting the `priority_steps` transport option, which must be a list of numbers in sorted order:

```python
>>> BROKER_TRANSPORT_OPTIONS = {
...     'priority_steps': [0, 2, 4, 6, 8, 9],
... }
```
Priorities implemented in this way isn’t as reliable as priorities on the server side, which is why the feature is nicknamed “quasi-priorities”; **Using routing is still the suggested way of ensuring quality of service**, as client implemented priorities fall short in a number of ways, for example if the worker is busy with long running tasks, has prefetched many messages, or the queues are congested.

Still, it is possible that using priorities in combination with routing can be more beneficial than using routing or priorities alone. Experimentation and monitoring should be used to prove this.

Contributed by Germán M. Bravo.

**Redis: Now cycles queues so that consuming is fair**

This ensures that a very busy queue won’t block messages from other queues, and ensures that all queues have an equal chance of being consumed from.

This used to be the case before, but the behavior was accidentally changed while switching to using blocking pop.

**group/chord/chain are now subtasks**

- group is no longer an alias to TaskSet, but new all together, since it was very difficult to migrate the TaskSet class to become a subtask.
- A new shortcut has been added to tasks:

  ```
  >>> task.s(arg1, arg2, kw=1)
  ```

  as a shortcut to:

  ```
  >>> task.subtask((arg1, arg2), {'kw': 1})
  ```

- Tasks can be chained by using the | operator:

  ```
  >>> (add.s(2, 2), pow.s(2)).apply_async()
  ```

- Subtasks can be “evaluated” using the ~ operator:

  ```
  >>> ~(add.s(2, 2))
  4
  >>> ~(add.s(2, 2) | pow.s(2))
  ```

  is the same as:

  ```
  >>> chain(add.s(2, 2), pow.s(2)).apply_async().get()
  ```

- A new subtask_type key has been added to the subtask dictionary.
  This can be the string "chord", "group", "chain", "chunks", "xmap", or "xstarmap".
- maybe_subtask now uses subtask_type to reconstruct the object, to be used when using non-pickle serializers.
- The logic for these operations have been moved to dedicated tasks celery.chord, celery.chain and celery.group.
- subtask no longer inherits from AttributeDict.

  It’s now a pure dict subclass with properties for attribute access to the relevant keys.
- The repr’s now outputs how the sequence would like imperatively:
```python
>>> from celery import chord

>>> (chord([add.s(i, i) for i in xrange(10)], xsum.s())
    | pow.s(2))

tasks.xsum([tasks.add(0, 0),
            tasks.add(1, 1),
            tasks.add(2, 2),
            tasks.add(3, 3),
            tasks.add(4, 4),
            tasks.add(5, 5),
            tasks.add(6, 6),
            tasks.add(7, 7),
            tasks.add(8, 8),
            tasks.add(9, 9)]) | tasks.pow(2)
```

### New remote control commands

These commands were previously experimental, but they’ve proven stable and is now documented as part of the official API.

- **add_consumer/cancel_consumer**

  Tells workers to consume from a new queue, or cancel consuming from a queue. This command has also been changed so that the worker remembers the queues added, so that the change will persist even if the connection is re-connected.

  These commands are available programmatically as `app.control.add_consumer()` / `app.control.cancel_consumer()`:

  ```python
  >>> celery.control.add_consumer(queue_name,
                                 ...     destination=['w1.example.com'])
  >>> celery.control.cancel_consumer(queue_name,
                                     ...     destination=['w1.example.com'])
  ```

  or using the `celery control` command:

  ```
  $ celery control -d w1.example.com add_consumer queue
  $ celery control -d w1.example.com cancel_consumer queue
  ```

  **Note:** Remember that a control command without `destination` will be sent to all workers.

- **autoscale**

  Tells workers with `--autoscale` enabled to change autoscale max/min concurrency settings.

  This command is available programmatically as `app.control.autoscale()`:

  ```python
  >>> celery.control.autoscale(max=10, min=5,
                              ...     destination=['w1.example.com'])
  ```

  or using the `celery control` command:

  ```
  $ celery control -d w1.example.com autoscale 10 5
  ```

- **pool_grow/pool_shrink**
Tells workers to add or remove pool processes.

These commands are available programmatically as `app.control.pool_grow()` / `app.control.pool_shrink()`:

```python
>>> celery.control.pool_grow(2, destination=['w1.example.com'])
>>> celery.control.pool_shrink(2, destination=['w1.example.com'])
```

or using the `celery control` command:

```bash
$ celery control -d w1.example.com pool_grow 2
$ celery control -d w1.example.com pool_shrink 2
```

• `celery control` now supports `rate_limit` and `time_limit` commands. See `celery control --help` for details.

**Crontab now supports Day of Month, and Month of Year arguments**

See the updated list of examples at *Crontab schedules*.

**Immutable subtasks**

Subtasks can now be immutable, which means that the arguments won’t be modified when calling callbacks:

```python
>>> chain(add.s(2, 2), clear_static_electricity.si())
```

means it'll not receive the argument of the parent task, and `.si()` is a shortcut to:

```python
>>> clear_static_electricity.subtask(immutable=True)
```

**Logging Improvements**

Logging support now conforms better with best practices.

• Classes used by the worker no longer uses `app.get_default_logger`, but uses `celery.utils.log.get_logger` which simply gets the logger not setting the level, and adds a NullHandler.

• Loggers are no longer passed around, instead every module using logging defines a module global logger that’s used throughout.

• All loggers inherit from a common logger called “celery”.

• Before `task.get_logger` would setup a new logger for every task, and even set the log level. This is no longer the case.
  
  – Instead all task loggers now inherit from a common “celery.task” logger that’s set up when programs call `setup_logging_subsystem`.
  
  – Instead of using LoggerAdapter to augment the formatter with the task_id and task_name field, the task base logger now use a special formatter adding these values at run-time from the currently executing task.

• In fact, `task.get_logger` is no longer recommended, it is better to add a module-level logger to your tasks module.

  For example, like this:
from celery.utils.log import get_task_logger

logger = get_task_logger(__name__)

@celery.task
def add(x, y):
    logger.debug('Adding %r + %r' % (x, y))
    return x + y

The resulting logger will then inherit from the "celery.task" logger so that the current task name and id is included in logging output.

- Redirected output from stdout/stderr is now logged to a “celery.redirected” logger.
- In addition a few warnings.warn have been replaced with logger.warn.
- Now avoids the ‘no handlers for logger multiprocessing’ warning

**Task registry no longer global**

Every Celery instance now has its own task registry.

You can make apps share registries by specifying it:

```python
>>> app1 = Celery()
>>> app2 = Celery(tasks=app1.tasks)
```

Note that tasks are shared between registries by default, so that tasks will be added to every subsequently created task registry. As an alternative tasks can be private to specific task registries by setting the shared argument to the @task decorator:

```python
@celery.task(shared=False)
def add(x, y):
    return x + y
```

**Abstract tasks are now lazily bound**

The Task class is no longer bound to an app by default, it will first be bound (and configured) when a concrete subclass is created.

This means that you can safely import and make task base classes, without also initializing the app environment:

```python
from celery.task import Task
class DebugTask(Task):
    abstract = True

    def __call__(self, *args, **kwargs):
        print('CALLING %r % (self,))
        return self.run(*args, **kwargs)
```

```python
>>> DebugTask
<unbound DebugTask>
>>> @celery1.task(base=DebugTask)
```
... def add(x, y):
... return x + y

>>> add.__class__
<class add of <Celery default:0x101510d10>>

Lazy task decorators

The `@task` decorator is now lazy when used with custom apps.

That is, if `accept_magic_kwargs` is enabled (her by called “compat mode”), the task decorator executes inline like before, however for custom apps the `@task` decorator now returns a special PromiseProxy object that’s only evaluated on access.

All promises will be evaluated when `app.finalize()` is called, or implicitly when the task registry is first used.

Smart –`app` option

The `--app` option now ‘auto-detects’

- If the provided path is a module it tries to get an attribute named ‘celery’.
- If the provided path is a package it tries to import a sub module named celery’, and get the celery attribute from that module.

For example, if you have a project named `proj` where the celery app is located in `from proj.celery import app`, then the following will be equivalent:

```
$ celery worker --app=proj
$ celery worker --app=proj.celery:
$ celery worker --app=proj.celery:app
```

In Other News

- New `CELERYD_WORKER_LOST_WAIT` to control the timeout in seconds before billiard. `WorkerLostError` is raised when a worker can’t be signaled (Issue #595).
  Contributed by Brendon Crawford.
- Redis event monitor queues are now automatically deleted (Issue #436).
- App instance factory methods have been converted to be cached descriptors that creates a new subclass on access.
  For example, this means that `app.Worker` is an actual class and will work as expected when:

```
class Worker(app.Worker):
...
```

- New signal: `task_success`.
- Multiprocessing logs are now only emitted if the `MP_LOG` environment variable is set.
- The Celery instance can now be created with a broker URL

3.13. History
app = Celery(broker='redis://')

- Result backends can now be set using a URL
  Currently only supported by redis. Example use:

  ```
  CELERY_RESULT_BACKEND = 'redis://localhost/1'
  ```

- Heartbeat frequency now every 5s, and frequency sent with event
  The heartbeat frequency is now available in the worker event messages, so that clients can decide when to consider workers offline based on this value.

- Module celery.actors has been removed, and will be part of cl instead.

- Introduces new celery command, which is an entry-point for all other commands.
  The main for this command can be run by calling celery.start().

- Annotations now supports decorators if the key starts with `@`.
  For example:

  ```python
def debug_args(f):
    @wraps(f)
    def _inner(*args, **kwargs):
        print('ARGS: %r' % (args,))
        return _inner

  CELERY_ANNOTATIONS = {
    'tasks.add': {'@__call__': debug_args},
  }
  ```

  Also tasks are now always bound by class so that annotated methods end up being bound.

- Bug-report now available as a command and broadcast command
  - Get it from a Python REPL:
    ```
    >>> import celery
    >>> print(celery.bugreport())
    ```
  - Using the celery command line program:
    ```
    $ celery report
    ```
  - Get it from remote workers:
    ```
    $ celery inspect report
    ```

- Module celery.log moved to celery.app.log.

- Module celery.task.control moved to celery.app.control.

- New signal: task_revoked
  Sent in the main process when the task is revoked or terminated.

-AsyncResult.task_id renamed to AsyncResult.id
- TasksetResult.taskset_id renamed to .id
- `xmap(task, sequence)` and `xstarmap(task, sequence)`

  Returns a list of the results applying the task function to every item in the sequence.

  Example:
  ```python
  >>> from celery import xstarmap
  >>> xstarmap(add, zip(range(10), range(10))).apply_async()
  [0, 2, 4, 6, 8, 10, 12, 14, 16, 18]
  ```

- `chunks(task, sequence, chunksize)`

- `group.skew(start=, stop=, step=)`

  Skew will skew the countdown for the individual tasks in a group – for example with this group:
  ```python
  >>> g = group(add.s(i, i) for i in xrange(10))
  ```

  Skewing the tasks from 0 seconds to 10 seconds:
  ```python
  >>> g.skew(stop=10)
  ```

  Will have the first task execute in 0 seconds, the second in 1 second, the third in 2 seconds and so on.

- 99% test Coverage

- `CELERY_QUEUES` can now be a list/tuple of `Queue` instances.

  Internally `app.amqp.queues` is now a mapping of name/Queue instances, instead of converting on the fly.

- Can now specify connection for `app.control.inspect`.

  ```python
  from kombu import Connection
  i = celery.control.inspect(connection=Connection('redis://'))
  i.active_queues()
  ```

- `CELERY_FORCE_EXECV` is now enabled by default.

  If the old behavior is wanted the setting can be set to False, or the new `--no-execv` option to `celery worker`.

- Deprecated module `celery.conf` has been removed.

- The `CELERY_TIMEZONE` now always require the `pytz` library to be installed (except if the timezone is set to `UTC`).

- The Tokyo Tyrant backend has been removed and is no longer supported.

- Now uses `maybe_declare()` to cache queue declarations.

- There’s no longer a global default for the `CELERYBEAT_MAX_LOOP_INTERVAL` setting, it is instead set by individual schedulers.

- Worker: now truncates very long message bodies in error reports.

- No longer deep-copies exceptions when trying to serialize errors.

- `CELERY_BENCH` environment variable, will now also list memory usage statistics at worker shutdown.

- Worker: now only ever use a single timer for all timing needs, and instead set different priorities.

- An exceptions arguments are now safely pickled
Contributed by Matt Long.

- Worker/Beat no longer logs the start-up banner.
  Previously it would be logged with severity warning, now it’s only written to stdout.
- The contrib/ directory in the distribution has been renamed to extra/.
- New signal: task_revoked
- celery.contrib.migrate: Many improvements, including; filtering, queue migration, and support for
  acking messages on the broker migrating from.
  Contributed by John Watson.
- Worker: Prefetch count increments are now optimized and grouped together.
- Worker: No longer calls consume on the remote control command queue twice.
  Probably didn’t cause any problems, but was unnecessary.

Internals

- app.broker_connection is now app.connection
  Both names still work.
- Compatibility modules are now generated dynamically upon use.
  These modules are celery.messaging, celery.log, celery.decorators and
  celery.registry.
- celery.utils refactored into multiple modules:
  celery.utils.text celery.utils.imports celery.utils.functional
- Now using kombu.utils.encoding instead of celery.utils.encoding.
- Renamed module celery.routes -> celery.app.routes.
- Renamed package celery.db -> celery.backends.database.
- Renamed module celery.abstract -> celery.worker.bootsteps.
- Command line docs are now parsed from the module docstrings.
- Test suite directory has been reorganized.
- setup.py now reads docs from the requirements/ directory.
- Celery commands no longer wraps output (Issue #700).
  Contributed by Thomas Johansson.

Experimental

celery.contrib.methods: Task decorator for methods

This is an experimental module containing a task decorator, and a task decorator filter, that can be used to create tasks
out of methods:
from celery.contrib.methods import task_method

class Counter(object):
    def __init__(self):
        self.value = 1

@celery.task(name='Counter.increment', filter=task_method)
def increment(self, n=1):
    self.value += 1
    return self.value

See celery.contrib.methods for more information.

Unscheduled Removals

Usually we don’t make backward incompatible removals, but these removals should have no major effect.

- The following settings have been renamed:
  - CELERYD_ETA_SCHEDULER -> CELERYD_TIMER
  - CELERYD_ETA_SCHEDULER_PRECISION -> CELERYD_TIMER_PRECISION

Deprecation Time-line Changes

See the Celery Deprecation Time-line.

- The celery.backends.pyredis compat module has been removed.

  Use celery.backends.redis instead!

- The following undocumented API’s has been moved:

  - control.inspect.add_consumer -> app.control.add_consumer().
  - control.inspect.cancel_consumer -> app.control.cancel_consumer().
  - control.inspect.enable_events -> app.control.enable_events().
  - control.inspect.disable_events -> app.control.disable_events().

  This way inspect() is only used for commands that don’t modify anything, while idempotent control commands that make changes are on the control objects.

Fixes

- Retry SQLAlchemy backend operations on DatabaseError/OperationalError (Issue #634)
- Tasks that called retry wasn’t acknowledged if acks late was enabled

  Fix contributed by David Markey.

- The message priority argument wasn’t properly propagated to Kombu (Issue #708).

  Fix contributed by Eran Rundstein

3.0.24

release-date 2013-10-11 04:40 p.m. BST
release-by Ask Solem
• Now depends on Kombu 2.5.15.
• Now depends on billiard version 2.7.3.34.
• AMQP Result backend: No longer caches queue declarations.
The queues created by the AMQP result backend are always unique, so caching the declarations caused a slow memory leak.

- Worker: Fixed crash when hostname contained Unicode characters.
  Contributed by Daodao.

- The worker would no longer start if the `-P solo` pool was selected (Issue #1548).
- Redis/Cache result backends wouldn’t complete chords if any of the tasks were retried (Issue #1401).
- Task decorator is no longer lazy if app is finalized.
- AsyncResult: Fixed bug with copy(AsyncResult) when no current_app available.
- ResultSet: Now properly propagates app when passed string id’s.
- Loader now ignores `CELERY_CONFIG_MODULE` if value is empty string.
- Fixed race condition in Proxy object where it tried to delete an attribute twice, resulting in `AttributeError`.
- Task methods now works with the `CELERY_ALWAYS_EAGER` setting (Issue #1478).
- Broadcast queues were accidentally declared when publishing tasks (Issue #1540).
- New `C_FAKEFORK` environment variable can be used to debug the init-scripts.
  Setting this will skip the daemonization step so that errors printed to stderr after standard outs are closed can be seen:

```bash
$ C_FAKEFORK /etc/init.d/celeryd start
```

This works with the `celery multi` command in general.

- `get_pickleable_etype` didn’t always return a value (Issue #1556).
- Fixed bug where `app.GroupResult.restore` would fall back to the default app.
- Fixed rare bug where built-in tasks would use the current_app.
- `maybe_fileno()` now handles `ValueError`.

### 3.0.23

- **release-date** 2013-09-02 01:00 p.m. BST
- **release-by** Ask Solem

- Now depends on Kombu 2.5.14.
- `send_task` didn’t honor `link` and `link_error` arguments.
  This had the side effect of chains not calling unregistered tasks, silently discarding them.
  Fix contributed by Taylor Nelson.
- `celery.state`: Optimized precedence lookup.
  Contributed by Matt Robenolt.
- POSIX: Daemonization didn’t redirect `sys.stdin` to `/dev/null`.
  Fix contributed by Alexander Smirnov.
- Canvas: group bug caused fallback to default app when `.apply_async` used (Issue #1516)
- Canvas: generator arguments wasn’t always pickleable.
3.0.22

**release-date** 2013-08-16 04:30 p.m. BST

**release-by** Ask Solem

- Now depends on Kombu 2.5.13.
- Now depends on billiard 2.7.3.32
- Fixed bug with monthly and yearly Crontabs (Issue #1465).
  
  Fix contributed by Guillaume Gauvrit.
- Fixed memory leak caused by time limits (Issue #1129, Issue #1427)
- Worker will now sleep if being restarted more than 5 times in one second to avoid spamming with worker-online events.
- Includes documentation fixes
  
  Contributed by: Ken Fromm, Andreas Savvides, Alex Kiriukha, Michael Fladischer.

3.0.21

**release-date** 2013-07-05 04:30 p.m. BST

**release-by** Ask Solem

- Now depends on billiard 2.7.3.31.
  
  This version fixed a bug when running without the billiard C extension.
- 3.0.20 broke eventlet/gevent support (worker not starting).
- Fixed memory leak problem when MongoDB result backend was used with the gevent pool.
  
  Fix contributed by Ross Lawley.

3.0.20

**release-date** 2013-06-28 04:00 p.m. BST

**release-by** Ask Solem

- Contains workaround for deadlock problems.
  
  A better solution will be part of Celery 3.1.
- Now depends on Kombu 2.5.12.
- Now depends on billiard 2.7.3.30.
- --loader argument no longer supported importing loaders from the current directory.
- [Worker] Fixed memory leak when restarting after connection lost (Issue #1325).
- [Worker] Fixed UnicodeDecodeError at start-up (Issue #1373).
  
  Fix contributed by Jessica Tallon.
- [Worker] Now properly rewrites unpickleable exceptions again.
- Fixed possible race condition when evicting items from the revoked task set.
- [generic-init.d] Fixed compatibility with Ubuntu’s minimal Dash shell (Issue #1387).
Fix contributed by @monkut.

- Task.apply/ALWAYS_EAGER now also executes callbacks and errbacks (Issue #1336).
- [Worker] The worker-shutdown signal was no longer being dispatched (Issue #1339).
  Fix contributed by Xavier Ordoquy.

- [Python 3] Now handles io.UnsupportedOperation that may be raised by file.fileno() in Python 3.
- [events.State] Now ignores unknown event-groups.
- [MongoDB backend] No longer uses deprecated safe parameter.
  Fix contributed by @rfkrocktk.

- The eventlet pool now imports on Windows.
- [Canvas] Fixed regression where immutable chord members may receive arguments (Issue #1340).
  Fix contributed by Peter Brook.
- [Canvas] chain now accepts generator argument again (Issue #1319).
- celery.migrate command now consumes from all queues if no queues specified.
  Fix contributed by John Watson.

3.0.19

**release-date** 2013-04-17 04:30:00 p.m. BST

**release-by** Ask Solem

- Now depends on billiard 2.7.3.28
- A Python 3 related fix managed to disable the deadlock fix announced in 3.0.18.
  Tests have been added to make sure this doesn’t happen again.
- Task retry policy: Default max_retries is now 3.
  This ensures clients won’t be hanging while the broker is down.

**Note:** You can set a longer retry for the worker by using the celeryd_after_setup signal:

```python
from celery.signals import celeryd_after_setup

@celeryd_after_setup.connect
def configure_worker(instance, conf, **kwargs):
    conf.CELERY_TASK_PUBLISH_RETRY_POLICY = {
        'max_retries': 100,
        'interval_start': 0,
        'interval_max': 1,
        'interval_step': 0.2,
    }
```

- Worker: Will now properly display message body in error messages even if the body is a buffer instance.
• 3.0.18 broke the MongoDB result backend (Issue #1303).

3.0.18

release-date 2013-04-12 05:00:00 p.m. BST
release-by Ask Solem

• Now depends on kombu 2.5.10.
   See the kombu changelog.
• Now depends on billiard 2.7.3.27.
• Can now specify a white-list of accepted serializers using the new CELERY_ACCEPT_CONTENT setting.
   This means that you can force the worker to discard messages serialized with pickle and other untrusted serializers. For example to only allow JSON serialized messages use:
   
   ```
   CELERY_ACCEPT_CONTENT = ['json']
   ```
   
you can also specify MIME types in the white-list:
   
   ```
   CELERY_ACCEPT_CONTENT = ['application/json']
   ```

• Fixed deadlock in multiprocessing’s pool caused by the semaphore not being released when terminated by signal.
• Processes Pool: It’s now possible to debug pool processes using GDB.
• celery report now censors possibly secret settings, like passwords and secret tokens.
   You should still check the output before pasting anything on the internet.
• Connection URLs now ignore multiple ‘+’ tokens.
• Worker/statedb: Now uses pickle protocol 2 (Python 2.5+)
• Fixed Python 3 compatibility issues.
• Worker: A warning is now given if a worker is started with the same node name as an existing worker.
• Worker: Fixed a deadlock that could occur while revoking tasks (Issue #1297).
• Worker: The HUP handler now closes all open file descriptors before restarting to ensure file descriptors doesn’t leak (Issue #1270).
• Worker: Optimized storing/loading the revoked tasks list (Issue #1289).
   After this change the celery worker --statedb file will take up more disk space, but loading from and storing the revoked tasks will be considerably faster (what before took 5 minutes will now take less than a second).
• Celery will now suggest alternatives if there’s a typo in the broker transport name (e.g., ampq -> amqp).
• Worker: The auto-reloader would cause a crash if a monitored file was unlinked.
   Fix contributed by Agris Ameriks.
• Fixed AsyncResult pickling error.
   Fix contributed by Thomas Minor.
• Fixed handling of Unicode in logging output when using log colors (Issue #427).
• ConfigurationView is now a MutableMapping.
Contributed by Aaron Harnly.

- Fixed memory leak in LRU cache implementation.
  Fix contributed by Romuald Brunet.

- `celery.contrib.rdb`: Now works when sockets are in non-blocking mode.
  Fix contributed by Theo Spears.

- The `inspect reserved` remote control command included active (started) tasks with the reserved tasks (Issue #1030).

- The `task_failure` signal received a modified traceback object meant for pickling purposes, this has been fixed so that it now receives the real traceback instead.

- The `@task` decorator silently ignored positional arguments, it now raises the expected `TypeError` instead (Issue #1125).

- The worker will now properly handle messages with invalid ETA/expires fields (Issue #1232).

- The `pool_restart` remote control command now reports an error if the `CELERYD_POOL_RESTARTS` setting isn’t set.

- `add_defaults` can now be used with non-dict objects.

- Fixed compatibility problems in the Proxy class (Issue #1087).
  The class attributes `__module__`, `__name__` and `__doc__` are now meaningful string objects.
  Thanks to Marius Gedminas.

- MongoDB Backend: The `MONGODB_BACKEND_SETTINGS` setting now accepts a option key that lets you forward arbitrary kwargs to the underlying pymongo.Connection object (Issue #1015).

- Beat: The daily backend cleanup task is no longer enabled for result backends that support automatic result expiration (Issue #1031).

- Canvas list operations now takes application instance from the first task in the list, instead of depending on the `current_app` (Issue #1249).

- Worker: Message decoding error log message now includes traceback information.

- Worker: The start-up banner now includes system platform.

- `celery inspect|status|control` now gives an error if used with a SQL based broker transport.

3.0.17

**release-date** 2013-03-22 04:00:00 p.m. UTC

**release-by** Ask Solem

- Now depends on kombu 2.5.8
- Now depends on billiard 2.7.3.23

- RabbitMQ/Redis: thread-less and lock-free rate-limit implementation.
  This means that rate limits pose minimal overhead when used with RabbitMQ/Redis or future transports using the event-loop, and that the rate-limit implementation is now thread-less and lock-free.

  The thread-based transports will still use the old implementation for now, but the plan is to use the timer also for other broker transports in Celery 3.1.

- Rate limits now works with eventlet/gevent if using RabbitMQ/Redis as the broker.
• A regression caused `task.retry` to ignore additional keyword arguments.
  Extra keyword arguments are now used as execution options again. Fix contributed by Simon Engledew.

• Windows: Fixed problem with the worker trying to pickle the Django settings module at worker start-up.

• generic-init.d: No longer double quotes `$CELERYD_CHDIR` (Issue #1235).

• generic-init.d: Removes bash-specific syntax.
  Fix contributed by Pär Wieslander.

• Cassandra Result Backend: Now handles the `AllServersUnavailable` error (Issue #1010).
  Fix contributed by Jared Biel.

• Result: Now properly forwards apps to `GroupResult` when deserializing (Issue #1249).
  Fix contributed by Charles-Axel Dein.

• `GroupResult.revoke` now supports the `terminate` and `signal` keyword arguments.

• Worker: Multiprocessing pool workers now import task modules/configuration before setting up the logging system so that logging signals can be connected before they’re dispatched.

• chord: The `AsyncResult` instance returned now has its `parent` attribute set to the header `GroupResult`.
  This is consistent with how `chain` works.

### 3.0.16

**release-date** 2013-03-07 04:00:00 p.m. UTC

**release-by** Ask Solem

• Happy International Women’s Day!
  We have a long way to go, so this is a chance for you to get involved in one of the organizations working for making our communities more diverse.
  – PyLadies — http://pyladies.com

• Now depends on `kombu` version 2.5.7

• Now depends on `billiard` version 2.7.3.22

• AMQP heartbeats are now disabled by default.
  Some users experiences issues with heartbeats enabled, and it’s not strictly necessary to use them.
  If you’re experiencing problems detecting connection failures, you can re-enable heartbeats by configuring the `BROKER_HEARTBEAT` setting.

• Worker: Now propagates connection errors occurring in multiprocessing callbacks, so that the connection can be reset (Issue #1226).

• Worker: Now propagates connection errors occurring in timer callbacks, so that the connection can be reset.

• The modules in `CELERY_IMPORTS` and `CELERY_INCLUDE` are now imported in the original order (Issue #1161).
The modules in \texttt{CELERY\_IMPORTS} will be imported first, then continued by \texttt{CELERY\_INCLUDE}.

Thanks to Joey Wilhelm.

- New bash completion for \texttt{celery} available in the git repository:
  
  \url{https://github.com/celery/celery/tree/3.0/extra/bash-completion}

  You can source this file or put it in \texttt{bash\_completion.d} to get auto-completion for the \texttt{celery} command-line utility.

- The node name of a worker can now include unicode characters (Issue \#1186).
- The \texttt{repr} of a \texttt{crontab} object now displays correctly (Issue \#972).
- \texttt{events.State} no longer modifies the original event dictionary.
- No longer uses \texttt{Logger.warn} deprecated in Python 3.
- Cache Backend: Now works with chords again (Issue \#1094).
- Chord unlock now handles errors occurring while calling the callback.
- Generic worker init.d script: Status check is now performed by querying the pid of the instance instead of sending messages.

  Contributed by Milen Pavlov.

- Improved init-scripts for CentOS.
  
  – Updated to support Celery 3.x conventions.
  – Now uses CentOS built-in \texttt{status} and \texttt{killproc}
  – Support for multi-node / multi-pid worker services.
  – Standard color-coded CentOS service-init output.
  – A test suite.

  Contributed by Milen Pavlov.

- \texttt{ResultSet.join} now always works with empty result set (Issue \#1219).
- A group consisting of a single task is now supported (Issue \#1219).
- Now supports the \texttt{pycallgraph} program (Issue \#1051).
- Fixed Jython compatibility problems.
- Django tutorial: Now mentions that the example app must be added to \texttt{INSTALLED\_APPS} (Issue \#1192).

\textbf{3.0.15}

\textbf{release-date} 2013-02-11 04:30:00 p.m. UTC

\textbf{release-by}  Ask Solem

- Now depends on billiard 2.7.3.21 which fixed a syntax error crash.
- Fixed bug with \texttt{CELERY\_SEND\_TASK\_SENT\_EVENT}.
• Now depends on Kombu 2.5.6
• Now depends on billiard 2.7.3.20
• `execv` is now disabled by default.

It was causing too many problems for users, you can still enable it using the `CELERYD_FORCE_EXECV` setting.

`execv` was only enabled when transports other than AMQP/Redis was used, and it’s there to prevent deadlocks caused by mutexes not being released before the process forks. Unfortunately it also changes the environment introducing many corner case bugs that’re hard to fix without adding horrible hacks. Deadlock issues are reported far less often than the bugs that `execv` are causing, so we now disable it by default.

Work is in motion to create non-blocking versions of these transports so that `execv` isn’t necessary (which is the situation with the amqp and redis broker transports)

• Chord exception behavior defined (Issue #1172).

From Celery 3.1 the chord callback will change state to FAILURE when a task part of a chord raises an exception.

It was never documented what happens in this case, and the actual behavior was very unsatisfactory, indeed it will just forward the exception value to the chord callback.

For backward compatibility reasons we don’t change to the new behavior in a bugfix release, even if the current behavior was never documented. Instead you can enable the `CELERY_CHORD_PROPAGATES` setting to get the new behavior that’ll be default from Celery 3.1.

See more at Error handling.

• worker: Fixes bug with ignored and retried tasks.

The `on_chord_part_return` and `Task.after_return` callbacks, nor the `task_postrun` signal should be called when the task was retried/ignored.

Fix contributed by Vlad.

• `GroupResult.join_native` now respects the `propagate` argument.

• `subtask.id` added as an alias to `subtask['options'].id`

```python
>>> s = add.s(2, 2)
>>> s.id = 'my-id'
>>> s['options']
{'task_id': 'my-id'}

>>> s.id
'my-id'
```

• worker: Fixed error `Could not start worker processes` occurring when restarting after connection failure (Issue #1118).

• Adds new signal `task-retried` (Issue #1169).

• `celery events -dumper` now handles connection loss.
• Will now retry sending the task-sent event in case of connection failure.
• amqp backend: Now uses `Message.requeue` instead of republishing the message after poll.
• New `BROKER_HEARTBEAT_CHECKRATE` setting introduced to modify the rate at which broker connection heartbeats are monitored.
  The default value was also changed from 3.0 to 2.0.
• `celery.events.state.State` is now pickleable.
  Fix contributed by Mher Movsisyan.
• `celery.utils.functional.LRUCache` is now pickleable.
  Fix contributed by Mher Movsisyan.
• The stats broadcast command now includes the workers pid.
  Contributed by Mher Movsisyan.
• New `conf` remote control command to get a worker's current configuration.
  Contributed by Mher Movsisyan.
• Adds the ability to modify the chord unlock task’s countdown argument (Issue #1146).
  Contributed by Jun Sakai
• `beat`: The scheduler now uses the `now()` method of the schedule, so that schedules can provide a custom way to get the current date and time.
  Contributed by Raphaël Slinckx
• Fixed pickling of configuration modules on Windows or when `execv` is used (Issue #1126).
• Multiprocessing logger is now configured with loglevel `ERROR` by default.
  Since 3.0 the multiprocessing loggers were disabled by default (only configured when the `MP_LOG` environment variable was set).

### 3.0.13

**release-date** 2013-01-07 04:00:00 p.m. UTC
**release-by** Ask Solem

• Now depends on Kombu 2.5
  – `amqp` has replaced `amqplib` as the default transport, gaining support for AMQP 0.9, and the RabbitMQ extensions, including Consumer Cancel Notifications and heartbeats.
  – support for multiple connection URLs for failover.
  – Read more in the Kombu 2.5 changelog.
• Now depends on billiard 2.7.3.19
• Fixed a deadlock issue that could occur when the producer pool inherited the connection pool instance of the parent process.
• The `--loader` option now works again (Issue #1066).
• `celery` umbrella command: All sub-commands now supports the `--workdir` option (Issue #1063).
• Groups included in chains now give GroupResults (Issue #1057)
  Previously it would incorrectly add a regular result instead of a group result, but now this works:

---

3.13. History
• Chains can now chain other chains and use partial arguments (Issue #1057).

Example:

```python
>>> c1 = (add.s(2) | add.s(4))
>>> c2 = (add.s(8) | add.s(16))
>>> c3 = (c1 | c2)
>>> # 8 + 2 + 4 + 8 + 16
>>> assert c3(8).get() == 38
```

• Subtasks can now be used with unregistered tasks.

You can specify subtasks even if you just have the name:

```python
>>> s = subtask(task_name, args=(), kwargs=())
>>> s.delay()
```

• The `celery shell` command now always adds the current directory to the module path.

• The worker will now properly handle the `pytz.AmbiguousTimeError` exception raised when an ETA/countdown is prepared while being in DST transition (Issue #1061).

• `force_execv`: Now makes sure that task symbols in the original task modules will always use the correct app instance (Issue #1072).

• AMQP Backend: Now republishes result messages that have been polled (using `result.ready()` and friends, `result.get()` won’t do this in this version).

• Crontab schedule values can now “wrap around”

  This means that values like 11–1 translates to [11, 12, 1].

  Contributed by Loren Abrams.

• `multi stopwait` command now shows the pid of processes.

  Contributed by Loren Abrams.

• Handling of ETA/countdown fixed when the `CELERY_ENABLE_UTC` setting is disabled (Issue #1065).

• A number of unneeded properties were included in messages, caused by accidentally passing `Queue.as_dict` as message properties.

• Rate limit values can now be float

  This also extends the string format so that values like "0.5/s" works.

  Contributed by Christoph Krybus

• Fixed a typo in the broadcast routing documentation (Issue #1026).

• Rewrote confusing section about idempotence in the task user guide.

• Fixed typo in the daemonization tutorial (Issue #1055).
• Fixed several typos in the documentation.
  Contributed by Marius Gedminas.
• Batches: Now works when using the eventlet pool.
  Fix contributed by Thomas Grainger.
• Batches: Added example sending results to celery.contrib.batches.
  Contributed by Thomas Grainger.
• MongoDB backend: Connection max_pool_size can now be set in
  CELERY_MONGODB_BACKEND_SETTINGS.
  Contributed by Craig Younkins.
• Fixed problem when using earlier versions of pytz.
  Fix contributed by Vlad.
• Docs updated to include the default value for the CELERY_TASK_RESULT_EXPIRES setting.
• Improvements to the django-celery tutorial.
  Contributed by Locker537.
• The add_consumer control command didn’t properly persist the addition of new queues so that they survived connection failure (Issue #1079).

3.0.12

  release-date  2012-11-06 02:00 p.m. UTC
  release-by    Ask Solem
• Now depends on kombu 2.4.8
  – [Redis] New and improved fair queue cycle algorithm (Kevin McCarthy).
  – [Redis] Now uses a Redis-based mutex when restoring messages.
  – [Redis] Number of messages that can be restored in one interval is no longer limited (but can be set using the unacked_restore_limit transport option).
  – Heartbeat value can be specified in broker URLs (Mher Movsisyan).
  – Fixed problem with msgpack on Python 3 (Jasper Bryant-Greene).
• Now depends on billiard 2.7.3.18
• Celery can now be used with static analysis tools like PyDev/PyCharm/pylint etc.
• Development documentation has moved to Read The Docs.
  The new URL is: http://docs.celeryproject.org/en/master
• New CELERY_QUEUE_HA_POLICY setting used to set the default HA policy for queues when using RabbitMQ.
• New method Task.subtask_from_request returns a subtask using the current request.
• Results get_many method didn’t respect timeout argument.
  Fix contributed by Remigiusz Modrzejewski
• generic_init.d scripts now support setting CELERY_CREATE_DIRS to always create log and pid directories (Issue #1045).
This can be set in your `/etc/default/celeryd`.

- Fixed strange kombu import problem on Python 3.2 (Issue #1034).
- Worker: ETA scheduler now uses millisecond precision (Issue #1040).
- The `--config` argument to programs is now supported by all loaders.
- The `CASSANDRA_OPTIONS` setting has now been documented.

Contributed by Jared Biel.

- Task methods (`celery.contrib.methods`) cannot be used with the old task base class, the task decorator in that module now inherits from the new.
- An optimization was too eager and caused some logging messages to never emit.
- `celery.contrib.batches` now works again.
- Fixed missing white-space in `bdist_rpm` requirements (Issue #1046).
- Event state’s `tasks_by_name` applied limit before filtering by name.

Fix contributed by Alexander A. Sosnovskiy.

### 3.0.11

**release-date** 2012-09-26 04:00 p.m. UTC

**release-by** Ask Solem

- [security:low] generic-init.d scripts changed permissions of `/var/log` & `/var/run`

  In the daemonization tutorial the recommended directories were as follows:

  ```
  CELERYD_LOG_FILE="/var/log/celery/%n.log"
  CELERYD_PID_FILE="/var/run/celery/%n.pid"
  ```

  But in the scripts themselves the default files were `/var/log/celery%n.log` and `/var/run/celery%n.pid`, so if the user didn’t change the location by configuration, the directories `/var/log` and `/var/run` would be created - and worse have their permissions and owners changed.

  This change means that:
  - Default pid file is `/var/run/celery/%n.pid`
  - Default log file is `/var/log/celery/%n.log`
  - The directories are only created and have their permissions changed if *no custom locations are set*.

  Users can force paths to be created by calling the `create-paths` sub-command:

  ```
  $ sudo /etc/init.d/celeryd create-paths
  ```

**Upgrading Celery won’t update init-scripts**

To update the init-scripts you have to re-download the files from source control and update them manually. You can find the init-scripts for version 3.0.x at:

https://github.com/celery/celery/tree/3.0/extra/generic-init.d
• Now depends on billiard 2.7.3.17
• Fixes request stack protection when app is initialized more than once (Issue #1003).
• ETA tasks now properly works when system timezone isn’t same as the configured timezone (Issue #1004).
• Terminating a task now works if the task has been sent to the pool but not yet acknowledged by a pool process (Issue #1007).

    Fix contributed by Alexey Zatelepin
• Terminating a task now properly updates the state of the task to revoked, and sends a task-revoked event.
• Generic worker init-script now waits for workers to shutdown by default.
• Multi: No longer parses --app option (Issue #1008).
• Multi: stop_verify command renamed to stopwait.
• Daemonization: Now delays trying to create pidfile/logfile until after the working directory has been changed into.
• celery worker and celery beat commands now respects the --no-color option (Issue #999).
• Fixed typos in eventlet examples (Issue #1000)

    Fix contributed by Bryan Bishop. Congratulations on opening bug #1000!
• Tasks that raise Ignore are now acknowledged.
• Beat: Now shows the name of the entry in sending due task logs.

3.0.10

    release-date 2012-09-20 05:30 p.m. BST
    release-by Ask Solem
• Now depends on kombu 2.4.7
• Now depends on billiard 2.7.3.14
    – Fixes crash at start-up when using Django and pre-1.4 projects (setup_environ).
    – Hard time limits now sends the KILL signal shortly after TERM, to terminate processes that have signal handlers blocked by C extensions.
    – Billiard now installs even if the C extension cannot be built.

        It’s still recommended to build the C extension if you’re using a transport other than RabbitMQ/Redis (or use forced execv for some other reason).
    – Pool now sets a current_process().index attribute that can be used to create as many log files as there are processes in the pool.
• Canvas: chord/group/chain no longer modifies the state when called

    Previously calling a chord/group/chain would modify the ids of subtasks so that:

    >>> c = chord([add.s(2, 2), add.s(4, 4)], xsum.s())
    >>> c()
    >>> c() <-- call again

    at the second time the ids for the tasks would be the same as in the previous invocation. This is now fixed, so that calling a subtask won’t mutate any options.
- Canvas: Chaining a chord to another task now works (Issue #965).
- Worker: Fixed a bug where the request stack could be corrupted if relative imports are used.
  
  Problem usually manifested itself as an exception while trying to send a failed task result
  (NoneType does not have id attribute).
  
  Fix contributed by Sam Cooke.
- Tasks can now raise `Ignore` to skip updating states or events after return.
  
  Example:

  ```python
  from celery.exceptions import Ignore
  @task
def custom_revokes():
    if redis.sismember('tasks.revoked', custom_revokes.request.id):
      raise Ignore()
  ```
- The worker now makes sure the request/task stacks aren’t modified by the initial `Task.__call__`.
  
  This would previously be a problem if a custom task class defined `__call__` and also called `super()`.
- Because of problems the fast local optimization has been disabled, and can only be enabled by setting the
  `USE_FAST_LOCALS` attribute.
- Worker: Now sets a default socket timeout of 5 seconds at shutdown so that broken socket reads don’t hinder
  proper shutdown (Issue #975).
- More fixes related to late eventlet/gevent patching.
- Documentation for settings out of sync with reality:
  
  - `CELERY_TASK_PUBLISH_RETRY`
    
    Documented as disabled by default, but it was enabled by default since 2.5 as
    stated by the 2.5 changelog.
  
  - `CELERY_TASK_PUBLISH_RETRY_POLICY`
    
    The default max retries had been set to 100, but documented as being 3, and the
    interval_max was set to 1 but documented as 0.2. The default setting are now set
    to 3 and 0.2 as it was originally documented.
  
  Fix contributed by Matt Long.
- Worker: Log messages when connection established and lost have been improved.
- The repr of a Crontab schedule value of ‘0’ should be ‘*’ (Issue #972).
- Revoked tasks are now removed from reserved/active state in the worker (Issue #969)
  
  Fix contributed by Alexey Zatelepin.
- `gevent`: Now supports hard time limits using `gevent.Timeout`.
- Documentation: Links to init-scripts now point to the 3.0 branch instead of the development branch (master).
- Documentation: Fixed typo in signals user guide (Issue #986).
  
  ```
  instance.app.queues -> instance.app.amqp.queues.
  ```
- Eventlet/gevent: The worker didn’t properly set the custom app for new greenlets.
- Eventlet/gevent: Fixed a bug where the worker could not recover from connection loss (Issue #959).
Also, because of a suspected bug in gevent the `BROKER_CONNECTION_TIMEOUT` setting has been disabled when using gevent

3.0.9

**release-date** 2012-08-31 06:00 p.m. BST

**release-by** Ask Solem

- Important note for users of Django and the database scheduler!
    
    Recently a timezone issue has been fixed for periodic tasks, but erroneous timezones could have already been stored in the database, so for the fix to work you need to reset the `last_run_at` fields.

    You can do this by executing the following command:

```bash
$ python manage.py shell
>>> from djcelery.models import PeriodicTask
>>> PeriodicTask.objects.update(last_run_at=None)
```

You also have to do this if you change the timezone or `CELERY_ENABLE_UTC` setting.

- Note about the `CELERY_ENABLE_UTC` setting.
    
    If you previously disabled this just to force periodic tasks to work with your timezone, then you’re now encouraged to re-enable it.

- Now depends on Kombu 2.4.5 which fixes PyPy + Jython installation.

- Fixed bug with timezones when `CELERY_ENABLE_UTC` is disabled (Issue #952).

- Fixed a typo in the `celerybeat` upgrade mechanism (Issue #951).

- Make sure the `exc_info` argument to logging is resolved (Issue #899).

- Fixed problem with Python 3.2 and thread join timeout overflow (Issue #796).

- A test case was occasionally broken for Python 2.5.

- Unit test suite now passes for PyPy 1.9.

- App instances now supports the `with` statement.

    This calls the new `app.close()` method at exit, which cleans up after the app like closing pool connections.

    Note that this is only necessary when dynamically creating apps, for example “temporary” apps.

- Support for piping a subtask to a chain.

    For example:

    ```python
    pipe = sometask.s() | othertask.s()
    new_pipe = mytask.s() | pipe
    ```

    Contributed by Steve Morin.

- Fixed problem with group results on non-pickle serializers.

    Fix contributed by Steeve Morin.
3.0.8

**release-date** 2012-08-29 05:00 p.m. BST

**release-by** Ask Solem

- Now depends on Kombu 2.4.4
- Fixed problem with amqplib and receiving larger message payloads (Issue #922).
  
  The problem would manifest itself as either the worker hanging, or occasionally a **Framing error** exception appearing.
  
  Users of the new `pyamqp://` transport must upgrade to amqp 0.9.3.

- Beat: Fixed another timezone bug with interval and Crontab schedules (Issue #943).
- Beat: The schedule file is now automatically cleared if the timezone is changed.
  
  The schedule is also cleared when you upgrade to 3.0.8 from an earlier version, this to register the initial timezone info.

- Events: The `worker-heartbeat` event now include processed and active count fields.
  
  Contributed by Mher Movsisyan.

- Fixed error with error email and new task classes (Issue #931).

- `BaseTask.__call__` is no longer optimized away if it has been monkey patched.

- Fixed shutdown issue when using gevent (Issue #911 & Issue #936).
  
  Fix contributed by Thomas Meson.

3.0.7

**release-date** 2012-08-24 05:00 p.m. BST

**release-by** Ask Solem

- Fixes several problems with periodic tasks and timezones (Issue #937).
- Now depends on kombu 2.4.2
  
  - Redis: Fixes a race condition crash
  
  - Fixes an infinite loop that could happen when retrying establishing the broker connection.

- Daemons now redirect standard file descriptors to `/dev/null`
  
  Though by default the standard outs are also redirected to the logger instead, but you can disable this by changing the `CELERY_REDIRECT_STDOUTS` setting.

- Fixes possible problems when eventlet/gevent is patched too late.

- `LoggingProxy` no longer defines `fileno()` (Issue #928).

- Results are now ignored for the chord unlock task.
  
  Fix contributed by Steeve Morin.

- Cassandra backend now works if result expiry is disabled.
  
  Fix contributed by Steeve Morin.

- The traceback object is now passed to signal handlers instead of the string representation.
  
  Fix contributed by Adam DePue.
• Celery command: Extensions are now sorted by name.
• A regression caused the task-failed event to be sent with the exception object instead of its string representation.
• The worker daemon would try to create the pid file before daemonizing to catch errors, but this file wasn’t immediately released (Issue #923).
• Fixes Jython compatibility.
• billiard.forking_enable was called by all pools not just the processes pool, which would result in a useless warning if the billiard C extensions weren’t installed.

3.0.6

release-date  2012-08-17 11:00 p.m. Ask Solem
• Now depends on kombu 2.4.0
• Now depends on billiard 2.7.3.12
• Redis: Celery now tries to restore messages whenever there are no messages in the queue.
• Crontab schedules now properly respects CELERY_TIMEZONE setting.

    It’s important to note that Crontab schedules uses UTC time by default unless this setting is set.
    Issue #904 and django-celery #150.

• billiard.enable_forking is now only set by the processes pool.
• The transport is now properly shown by celery report (Issue #913).
• The –app argument now works if the last part is a module name (Issue #921).
• Fixed problem with unpickleable exceptions (billiard #12).
• Adds task_name attribute to EagerResult which is always None (Issue #907).
• Old Task class in celery.task no longer accepts magic kwargs by default (Issue #918).

    A regression long ago disabled magic kwargs for these, and since no one has complained about it we don’t have any incentive to fix it now.
• The inspect reserved control command didn’t work properly.
• Should now play better with tools for static analysis by explicitly specifying dynamically created attributes in the celery and celery.task modules.
• Terminating a task now results in RevokedTaskError instead of a WorkerLostError.
• AsyncResult.revoke now accepts terminate and signal arguments.
• The task_revoked event now includes new fields: terminated, signum, and expired.
• The argument to TaskRevokedError is now one of the reasons revoked, expired or terminated.
• Old Task class does no longer use classmethod for push_request and pop_request (Issue #912).
• GroupResult now supports the children attribute (Issue #916).
• AsyncResult.collect now respects the intermediate argument (Issue #917).
• Fixes example task in documentation (Issue #902).
• Eventlet fixed so that the environment is patched as soon as possible.
• eventlet: Now warns if Celery related modules that depends on threads are imported before eventlet is patched.
• Improved event and camera examples in the monitoring guide.
• Disables celery command setuptools entry-points if the command can’t be loaded.
• Fixed broken `dump_request` example in the tasks guide.

3.0.5

release-date 2012-08-01 04:00 p.m. BST
release-by  Ask Solem

• Now depends on kombu 2.3.1 + billiard 2.7.3.11
• Fixed a bug with the -B option (cannot pickle thread.lock objects) (Issue #894 + Issue #892, +
django-celery #154).
• The restart_pool control command now requires the CELERYD_POOL_RESTARTS setting to be enabled
  This change was necessary as the multiprocessing event that the restart command depends on is
  responsible for creating many semaphores/file descriptors, resulting in problems in some environ-
  ments.
• `chain.apply` now passes args to the first task (Issue #889).
• Documented previously secret options to the django-celery monitor in the monitoring user guide (Issue #396).
• Old changelog are now organized in separate documents for each series, see History.

3.0.4

release-date 2012-07-26 07:00 p.m. BST
release-by  Ask Solem

• Now depends on Kombu 2.3
• New experimental standalone Celery monitor: Flower
  See Flower: Real-time Celery web-monitor to read more about it!
  Contributed by Mher Movsisyan.
• Now supports AMQP heartbeats if using the new `pyamqp://` transport.
  – The `amqp` transport requires the `amqp` library to be installed:

```
$ pip install amqp
```
  – Then you need to set the transport URL prefix to `pyamqp://`.
  – The default heartbeat value is 10 seconds, but this can be changed using the
    `BROKER_HEARTBEAT` setting:

```
BROKER_HEARTBEAT = 5.0
```
  – If the broker heartbeat is set to 10 seconds, the heartbeats will be monitored every 5 seconds
    (double the heartbeat rate).
  See the Kombu 2.3 changelog for more information.
• Now supports RabbitMQ Consumer Cancel Notifications, using the `pyamqp://` transport.
This is essential when running RabbitMQ in a cluster. See the Kombu 2.3 changelog for more information.

- Delivery info is no longer passed directly through.
  
  It was discovered that the SQS transport adds objects that can’t be pickled to the delivery info mapping, so we had to go back to using the white-list again.
  
  Fixing this bug also means that the SQS transport is now working again.

- The semaphore wasn’t properly released when a task was revoked (Issue #877).
  
  This could lead to tasks being swallowed and not released until a worker restart.
  
  Thanks to Hynek Schlawack for debugging the issue.

- Retrying a task now also forwards any linked tasks.
  
  This means that if a task is part of a chain (or linked in some other way) and that even if the task is retried, then the next task in the chain will be executed when the retry succeeds.

- Chords: Now supports setting the interval and other keyword arguments to the chord unlock task.
  
  - The interval can now be set as part of the chord subtasks kwargs:
    
    ```python
    chord(header)(body, interval=10.0)
    ```
  
  - In addition the chord unlock task now honors the Task.default_retry_delay option, used when none is specified, which also means that the default interval can also be changed using annotations:
    
    ```python
    CELERY_ANNOTATIONS = {
        'celery.chord_unlock': {
            'default_retry_delay': 10.0,
        }
    }
    ```

- New `app.add_defaults()` method can add new default configuration dictionaries to the applications configuration.

  For example:

  ```python
  config = {'FOO': 10}
  app.add_defaults(config)
  ```

  is the same as `app.conf.update(config)` except that data won’t be copied, and that it won’t be pickled when the worker spawns child processes.

  In addition the method accepts a callable:

  ```python
  def initialize_config():
      # insert heavy stuff that can't be done at import time here.
  app.add_defaults(initialize_config)
  ```

  which means the same as the above except that it won’t happen until the Celery configuration is actually used.

  As an example, Celery can lazily use the configuration of a Flask app:
Celery Documentation, Release 4.4.0

```python
flask_app = Flask()
app = Celery()
app.add_defaults(lambda: flask_app.config)
```

- Revoked tasks weren’t marked as revoked in the result backend (Issue #871).
  
  Fix contributed by Hynek Schlawack.

- Event-loop now properly handles the case when the `epoll` poller object has been closed (Issue #882).

- Fixed syntax error in `funtests/test_leak.py`
  
  Fix contributed by Catalin Iacob.

- group/chunks: Now accepts empty task list (Issue #873).

- New method names:
  
  - `Celery.default_connection()` `connection_or_acquire()`.
  
  - `Celery.default_producer()` `producer_or_acquire()`.

  The old names still work for backward compatibility.

### 3.0.3

**release-date** 2012-07-20 09:17 p.m. BST

**release-by** Ask Solem

- `amqplib` passes the channel object as part of the delivery_info and it’s not pickleable, so we now remove it.

### 3.0.2

**release-date** 2012-07-20 04:00 p.m. BST

**release-by** Ask Solem

- A bug caused the following task options to not take defaults from the configuration (Issue #867 + Issue #858)

  The following settings were affected:

  - `CELERY_IGNORE_RESULT`
  
  - `CELERYD_SEND_TASK_ERROR_EMAILS`
  
  - `CELERY_TRACK_STARTED`
  
  - `CELERY_STORE_ERRORS_EVEN_IF_IGNORED`

  Fix contributed by John Watson.

- Task Request: `delivery_info` is now passed through as-is (Issue #807).

- The ETA argument now supports datetime’s with a timezone set (Issue #855).

- The worker’s banner displayed the autoscale settings in the wrong order (Issue #859).

- Extension commands are now loaded after concurrency is set up so that they don’t interfere with things like eventlet patching.

- Fixed bug in the threaded pool (Issue #863)

- The task failure handler mixed up the fields in `sys.exc_info()`.
Fix contributed by Rinat Shigapov.

- Fixed typos and wording in the docs.
  Fix contributed by Paul McMillan

- **New setting:** CELERY_WORKER_DIRECT
  If enabled each worker will consume from their own dedicated queue which can be used to route tasks to specific workers.

- Fixed several edge case bugs in the add consumer remote control command.

- **migrate:** Can now filter and move tasks to specific workers if CELERY_WORKER_DIRECT is enabled.

  Among other improvements, the following functions have been added:

  - `move_direct(filterfun, **opts)`
  - `move_direct_by_id(task_id, worker_hostname, **opts)`
  - `move_direct_by_idmap({task_id: worker_hostname, ...}, **opts)`
  - `move_direct_by_taskmap({task_name: worker_hostname, ...}, **opts)`

- `default_connection()` now accepts a pool argument that if set to false causes a new connection to be created instead of acquiring one from the pool.

- New signal: `celeryd_after_setup`.

- Default loader now keeps lowercase attributes from the configuration module.

### 3.0.1

**release-date** 2012-07-10 06:00 p.m. BST

**release-by** Ask Solem

- Now depends on kombu 2.2.5

- `inspect` now supports limit argument:

  ```python
  myapp.control.inspect(limit=1).ping()
  ```

- Beat: now works with timezone aware datetime’s.

- Task classes inheriting from `celery import Task` mistakenly enabled `accept_magic_kwargs`.

- Fixed bug in `inspect scheduled` (Issue #829).

- Beat: Now resets the schedule to upgrade to UTC.

- The `celery worker` command now works with eventlet/gevent.

  Previously it wouldn’t patch the environment early enough.

- The `celery` command now supports extension commands using setuptools entry-points.

  Libraries can add additional commands to the `celery` command by adding an entry-point like:
The command must then support the interface of `celery.bin.base.Command`.

- contrib.migrate: New utilities to move tasks from one queue to another.
  - `move_tasks()`
  - `move_task_by_id()`
- The `task-sent` event now contains `exchange` and `routing_key` fields.
- Fixes bug with installing on Python 3.
  Fix contributed by Jed Smith.

### 3.0.0 (Chiastic Slide)

- **release-date**  2012-07-07 01:30 p.m. BST
- **release-by**   Ask Solem

See *What's new in Celery 3.0 (Chiastic Slide)*.

### 3.13.11 What’s new in Celery 2.5

Celery aims to be a flexible and reliable, best-of-breed solution to process vast amounts of messages in a distributed fashion, while providing operations with the tools to maintain such a system.

Celery has a large and diverse community of users and contributors, you should come join us on IRC or our mailing-list.

To read more about Celery you should visit our website.

While this version is backward compatible with previous versions it’s important that you read the following section.

If you use Celery in combination with Django you must also read the `django-celery changelog <djcelery:version-2.5.0>` and upgrade to `django-celery 2.5`.

This version is officially supported on CPython 2.5, 2.6, 2.7, 3.2 and 3.3, as well as PyPy and Jython.

- **Important Notes**
  - Broker connection pool now enabled by default
  - Rabbit Result Backend: Exchange is no longer auto delete
  - Solution for hanging workers (but must be manually enabled)
- **Optimization**
- **Deprecation Time-line Changes**
  - Removals
– Deprecated modules

• News
  – Timezone support
  – New security serializer using cryptographic signing
  – New CELERY_ANNOTATIONS setting
  – current provides the currently executing task
  – In Other News

• Fixes

Important Notes

Broker connection pool now enabled by default

The default limit is 10 connections, if you have many threads/green-threads using connections at the same time you may want to tweak this limit to avoid contention.

See the BROKER_POOL_LIMIT setting for more information.

Also note that publishing tasks will be retried by default, to change this default or the default retry policy see CELERY_TASK_PUBLISH_RETRY and CELERY_TASK_PUBLISH_RETRY_POLICY.

Rabbit Result Backend: Exchange is no longer auto delete

The exchange used for results in the Rabbit (AMQP) result backend used to have the auto_delete flag set, which could result in a race condition leading to an annoying warning.

For RabbitMQ users

Old exchanges created with the auto_delete flag enabled has to be removed.

The camqadm command can be used to delete the previous exchange:

```bash
$ camqadm exchange.delete celeryresults
```

As an alternative to deleting the old exchange you can configure a new name for the exchange:

```
CELERY_RESULT_EXCHANGE = 'celeryresults2'
```

But you have to make sure that all clients and workers use this new setting, so they’re updated to use the same exchange name.

Solution for hanging workers (but must be manually enabled)

The CELERYD_FORCE_EXECV setting has been added to solve a problem with deadlocks that originate when threads and fork is mixed together:

```
CELERYD_FORCE_EXECV = True
```
This setting is recommended for all users using the prefork pool, but especially users also using time limits or a max tasks per child setting.

- See Python Issue 6721 to read more about this issue, and why resorting to `execv`() is the only safe solution. Enabling this option will result in a slight performance penalty when new child worker processes are started, and it will also increase memory usage (but many platforms are optimized, so the impact may be minimal). Considering that it ensures reliability when replacing lost worker processes, it should be worth it.
  - It’s already the default behavior on Windows.
  - It will be the default behavior for all platforms in a future version.

**Optimization**

- The code path used when the worker executes a task has been heavily optimized, meaning the worker is able to process a great deal more tasks/second compared to previous versions. As an example the solo pool can now process up to 15000 tasks/second on a 4 core MacBook Pro when using the pylibrabbitmq transport, where it previously could only do 5000 tasks/second.
  - The task error tracebacks are now much shorter.
  - Fixed a noticeable delay in task processing when rate limits are enabled.

**Deprecation Time-line Changes**

**Removals**

- The old TaskSet signature of (task_name, list_of_tasks) can no longer be used (originally scheduled for removal in 2.4). The deprecated .task_name and .task attributes has also been removed.
- The functions `celery.execute.delay_task`, `celery.execute.apply`, and `celery.execute.apply_async` has been removed (originally scheduled for removal in 2.3).
- The built-in ping task has been removed (originally scheduled for removal in 2.3). Please use the ping broadcast command instead.
- It’s no longer possible to import `subtask` and `TaskSet` from `celery.task.base`, please import them from `celery.task` instead (originally scheduled for removal in 2.4).

**Deprecated modules**

- The `celery.decorators` module has changed status from pending deprecation to deprecated, and is scheduled for removal in version 4.0. The `celery.task` module must be used instead.

**News**

**Timezone support**

Celery can now be configured to treat all incoming and outgoing dates as UTC, and the local timezone can be configured.

This isn’t yet enabled by default, since enabling time zone support means workers running versions pre-2.5 will be out of sync with upgraded workers.

To enable UTC you have to set `CELERY_ENABLE_UTC`: 
CELERY_ENABLE_UTC = True

When UTC is enabled, dates and times in task messages will be converted to UTC, and then converted back to the local timezone when received by a worker.

You can change the local timezone using the CELERY_TIMEZONE setting. Installing the pytz library is recommended when using a custom timezone, to keep timezone definition up-to-date, but it will fallback to a system definition of the timezone if available.

UTC will enabled by default in version 3.0.

Note: django-celery will use the local timezone as specified by the TIME_ZONE setting, it will also honor the new USE_TZ setting introduced in Django 1.4.

New security serializer using cryptographic signing

A new serializer has been added that signs and verifies the signature of messages.

The name of the new serializer is auth, and needs additional configuration to work (see Security).

See also:

Security

Contributed by Mher Movsisyan.

New CELERY_ANNOTATIONS setting

This new setting enables the configuration to modify task classes and their attributes.

The setting can be a dict, or a list of annotation objects that filter for tasks and return a map of attributes to change.

As an example, this is an annotation to change the rate_limit attribute for the tasks.add task:

CELERY_ANNOTATIONS = {'tasks.add': {'rate_limit': '10/s'}}

or change the same for all tasks:

CELERY_ANNOTATIONS = {'*': {'rate_limit': '10/s'}}

You can change methods too, for example the on_failure handler:

```
def my_on_failure(self, exc, task_id, args, kwargs, einfo):
    print('Oh no! Task failed: %r % (exc,))

CELERY_ANNOTATIONS = {'*': {'on_failure': my_on_failure}}
```

If you need more flexibility then you can also create objects that filter for tasks to annotate:

```
class MyAnnotate(object):
    def annotate(self, task):
        if task.name.startswith('tasks. '):
            return {'rate_limit': '10/s'}

CELERY_ANNOTATIONS = (MyAnnotate(), {other_annotations,})
```
current provides the currently executing task

The new celery.task.current proxy will always give the currently executing task.

Example:

```python
from celery.task import current, task
@task
def update_twitter_status(auth, message):
    twitter = Twitter(auth)
    try:
        twitter.update_status(message)
    except twitter.FailWhale, exc:
        # retry in 10 seconds.
        current.retry(countdown=10, exc=exc)
```

Previously you’d’ve to type `update_twitter_status.retry(...) here, which can be annoying for long task names.

**Note:** This won’t work if the task function is called directly (i.e., `update_twitter_status(a, b)`). For that to work `apply` must be used: `update_twitter_status.apply((a, b))`.

In Other News

- Now depends on Kombu 2.1.0.
- Efficient Chord support for the Memcached backend (Issue #533)
  
  This means Memcached joins Redis in the ability to do non-polling chords.
  
  Contributed by Dan McGee.

- Adds Chord support for the Rabbit result backend (amqp)
  
  The Rabbit result backend can now use the fallback chord solution.

- Sending QUIT to celeryd will now cause it cold terminate.
  
  That is, it won’t finish executing the tasks it’s currently working on.
  
  Contributed by Alec Clowes.

- New “detailed” mode for the Cassandra backend.
  
  Allows to have a “detailed” mode for the Cassandra backend. Basically the idea is to keep all states using Cassandra wide columns. New states are then appended to the row as new columns, the last state being the last column.

  See the CASSANDRA_DETAILED_MODE setting.
  
  Contributed by Steeve Morin.

- The Crontab parser now matches Vixie Cron behavior when parsing ranges with steps (e.g., 1-59/2).
  
  Contributed by Daniel Hepper.

- celerybeat can now be configured on the command-line like celeryd.
  
  Additional configuration must be added at the end of the argument list followed by --, for example:
Celery Documentation, Release 4.4.0

```
$ celerybeat -l info -- celerybeat.max_loop_interval=10.0
```

- Now limits the number of frames in a traceback so that `celeryd` doesn’t crash on maximum recursion limit exceeded exceptions (Issue #615).
  
  The limit is set to the current recursion limit divided by 8 (which is 125 by default).

  To get or set the current recursion limit use `sys.getrecursionlimit()` and `sys.setrecursionlimit()`.

- More information is now preserved in the pickleable traceback.

  This has been added so that Sentry can show more details.

  Contributed by Sean O’Connor.

- CentOS init-script has been updated and should be more flexible.

  Contributed by Andrew McFague.

- MongoDB result backend now supports `forget()`.

  Contributed by Andrew McFague

- `task.retry()` now re-raises the original exception keeping the original stack trace.

  Suggested by @ojii.

- The –uid argument to daemons now uses `initgroups()` to set groups to all the groups the user is a member of.

  Contributed by Łukasz Oleś.

- `celeryctl`: Added shell command.

  The shell will have the current_app (celery) and all tasks automatically added to locals.

- `celeryctl`: Added migrate command.

  The migrate command moves all tasks from one broker to another. Note that this is experimental and you should have a backup of the data before proceeding.

  **Examples:**

  ```
  $ celeryctl migrate redis://localhost amqp://localhost
  $ celeryctl migrate amqp://localhost//v1 amqp://localhost//v2
  $ python manage.py celeryctl migrate django:// redis://
  ```

- Routers can now override the exchange and routing_key used to create missing queues (Issue #577).

  By default this will always use the name of the queue, but you can now have a router return exchange and routing_key keys to set them.

  This is useful when using routing classes which decides a destination at run-time.

  Contributed by Akira Matsuzaki.

- Redis result backend: Adds support for a `max_connections` parameter.

  It’s now possible to configure the maximum number of simultaneous connections in the Redis connection pool used for results.

  The default max connections setting can be configured using the `CELERY_REDIS_MAX_CONNECTIONS` setting, or it can be changed individually by `RedisBackend(max_connections=int)`.  

3.13. History
Contributed by Steeve Morin.

- Redis result backend: Adds the ability to wait for results without polling.
  Contributed by Steeve Morin.
- MongoDB result backend: Now supports save and restore taskset.
  Contributed by Julien Poissonnier.
- There's a new Security guide in the documentation.
- The init-scripts have been updated, and many bugs fixed.
  Contributed by Chris Streeter.
- User (tilde) is now expanded in command-line arguments.
- Can now configure CELERYCTL environment variable in /etc/default/celeryd.
  While not necessary for operation, celeryctl is used for the celeryd status command, and the path to celeryctl must be configured for that to work.
  The daemonization cookbook contains examples.
  Contributed by Jude Nagurney.
- The MongoDB result backend can now use Replica Sets.
  Contributed by Ivan Metzlar.
- gevent: Now supports autoscaling (Issue #599).
  Contributed by Mark Lavin.
- multiprocessing: Mediator thread is now always enabled, even though rate limits are disabled, as the pool semaphore is known to block the main thread, causing broadcast commands and shutdown to depend on the semaphore being released.

Fixes

- Exceptions that are re-raised with a new exception object now keeps the original stack trace.
- Windows: Fixed the no handlers found for multiprocessing warning.
- Windows: The celeryd program can now be used.
  Previously Windows users had to launch celeryd using python -m celery.bin.
  celeryd.
- Redis result backend: Now uses SETEX command to set result key, and expiry atomically.
  Suggested by @yaniv-aknin.
- celeryd: Fixed a problem where shutdown hanged when Control-c was used to terminate.
- celeryd: No longer crashes when channel errors occur.
  Fix contributed by Roger Hu.
- Fixed memory leak in the eventlet pool, caused by the use of greenlet.getcurrent.
  Fix contributed by Ignas Mikalajunas.
- Cassandra backend: No longer uses pycassa.connect() which is deprecated since pycassa 1.4.
  Fix contributed by Jeff Terrace.
• Fixed unicode decode errors that could occur while sending error emails.
  Fix contributed by Seong Wun Mun.
• `celery.bin` programs now always defines `__package__` as recommended by PEP-366.
• `send_task` now emits a warning when used in combination with `CELERY_ALWAYS_EAGER` (Issue #581).
  Contributed by Mher Movsisyan.
• `apply_async` now forwards the original keyword arguments to `apply` when `CELERY_ALWAYS_EAGER` is enabled.
• `celeryev` now tries to re-establish the connection if the connection to the broker is lost (Issue #574).
• `celeryev`: Fixed a crash occurring if a task has no associated worker information.
  Fix contributed by Matt Williamson.
• The current date and time is now consistently taken from the current loaders `now` method.
• Now shows helpful error message when given a configuration module ending in `.py` that can’t be imported.
• `celeryctl`: The `--expires` and `--eta` arguments to the `apply` command can now be an ISO-8601 formatted string.
• `celeryctl` now exits with exit status `EX_UNAVAILABLE` (69) if no replies have been received.

### 3.13.12 Change history for Celery 2.5

This document contains change notes for bugfix releases in the 2.5.x series, please see *What’s new in Celery 2.5* for an overview of what’s new in Celery 2.5.

If you’re looking for versions prior to 2.5 you should visit our *History* of releases.

#### 2.5.5

**release-date** 2012-06-06 04:00 p.m. BST

**release-by** Ask Solem

This is a dummy release performed for the following goals:
• Protect against force upgrading to Kombu 2.2.0
• Version parity with django-celery
2.5.3

release-date  2012-04-16 07:00 p.m. BST
release-by   Ask Solem

- A bug causes messages to be sent with UTC time-stamps even though CELERY_ENABLE_UTC wasn’t enabled (Issue #636).
- celerybeat: No longer crashes if an entry’s args is set to None (Issue #657).
- Auto-reload didn’t work if a module’s __file__ attribute was set to the module’s .pyc file. (Issue #647).
- Fixes early 2.5 compatibility where __package__ doesn’t exist (Issue #638).

2.5.2

release-date  2012-04-13 04:30 p.m. GMT
release-by   Ask Solem

News

- Now depends on Kombu 2.1.5.
- Django documentation has been moved to the main Celery docs.
  See Django.
- New celeryd_init signal can be used to configure workers by hostname.
- Signal.connect can now be used as a decorator.
  Example:

  ```python
  from celery.signals import task_sent
  @task_sent.connect
  def on_task_sent(**kwargs):
      print('sent task: %r' % (kwargs,))
  ```

- Invalid task messages are now rejected instead of acked.
  This means that they will be moved to the dead-letter queue introduced in the latest RabbitMQ version (but must be enabled manually, consult the RabbitMQ documentation).
- Internal logging calls has been cleaned up to work better with tools like Sentry.
  Contributed by David Cramer.
- New method subtask.clone() can be used to clone an existing subtask with augmented arguments/options.
  Example:

  ```python
  >>> s = add.subtask((5,))
  >>> new = s.clone(args=(10,), countdown=5)
  >>> new.args
  (10, 5)
  >>> new.options
  {'countdown': 5}
  ```
• Chord callbacks are now triggered in eager mode.

Fixes

• Programs now verifies that the pidfile is actually written correctly (Issue #641).
  Hopefully this will crash the worker immediately if the system is out of space to store the complete
  pidfile.
  In addition, we now verify that existing pidfiles contain a new line so that a partially written pidfile
  is detected as broken, as before doing:
  
  ```
  $ echo -n "1" > celeryd.pid
  ```
  
  would cause the worker to think that an existing instance was already running (init has pid 1 after
  all).

• Fixed 2.5 compatibility issue with use of print_exception.
  Fix contributed by Martin Melin.

• Fixed 2.5 compatibility issue with imports.
  Fix contributed by Iurii Kriachko.

• All programs now fix up __package__ when called as main.
  This fixes compatibility with Python 2.5.
  Fix contributed by Martin Melin.

• [celery control|inspect] can now be configured on the command-line.
  Like with the worker it is now possible to configure Celery settings on the command-line for celery
  controllinspect
  
  ```
  $ celery inspect -- broker.pool_limit=30
  ```

• Version dependency for python-dateutil fixed to be strict.
  Fix contributed by Thomas Meson.

• Task.__call__ is now optimized away in the task tracer rather than when the task class is created.
  This fixes a bug where a custom __call__ may mysteriously disappear.

• Auto-reload's inotify support has been improved.
  Contributed by Mher Movsisyan.

• The Django broker documentation has been improved.

• Removed confusing warning at top of routing user guide.

2.5.1

**release-date** 2012-03-01 01:00 p.m. GMT

**release-by** Ask Solem
Fixes

- Eventlet/Gevent: A small typo caused the worker to hang when eventlet/gevent was used, this was because the environment wasn’t monkey patched early enough.
- Eventlet/Gevent: Another small typo caused the mediator to be started with eventlet/gevent, which would make the worker sometimes hang at shutdown.
- `multiprocessing`: Fixed an error occurring if the pool was stopped before it was properly started.
- Proxy objects now redirects `__doc__` and `__name__` so `help(obj)` works.
- Internal timer (timer2) now logs exceptions instead of swallowing them (Issue #626).
- celery shell: can now be started with `--eventlet` or `--gevent` options to apply their monkey patches.

2.5.0

**release-date** 2012-02-24 04:00 p.m. GMT

**release-by** Ask Solem

See What’s new in Celery 2.5.

Since the changelog has gained considerable size, we decided to do things differently this time: by having separate “what’s new” documents for major version changes.

Bugfix releases will still be found in the changelog.

3.13.13 Change history for Celery 2.4

- 2.4.5
- 2.4.4
  - Security Fixes
  - Fixes
- 2.4.3
- 2.4.2
- 2.4.1
- 2.4.0
  - Important Notes
  - News

2.4.5

**release-date** 2011-12-02 05:00 p.m. GMT

**release-by** Ask Solem

- Periodic task interval schedules were accidentally rounded down, resulting in some periodic tasks being executed early.
• Logging of humanized times in the beat log is now more detailed.

• New Broker section in the Getting Started part of the Documentation

  This replaces the old “Other queues” tutorial, and adds documentation for MongoDB, Beanstalk and CouchDB.

2.4.4

release-date  2011-11-25 04:00 p.m. GMT
release-by   Ask Solem

Security Fixes

• [Security: CELERYSA-0001] Daemons would set effective id’s rather than real id’s when the --uid --gid arguments to celery multi, celeryd detach, celery beat and celery events were used.
  This means privileges weren’t properly dropped, and that it would be possible to regain supervisor privileges later.

Fixes

• Processes pool: Fixed rare deadlock at shutdown (Issue #523).
  Fix contributed by Ionel Maries Christian.

• Webhook tasks issued the wrong HTTP POST headers (Issue #515).
  The Content-Type header has been changed from application/json application/x-www-form-urlencoded, and adds a proper Content-Length header.
  Fix contributed by Mitar.

• Daemonization tutorial: Adds a configuration example using Django and virtualenv together (Issue #505).
  Contributed by Juan Ignacio Catalano.

• generic init-scripts now automatically creates log and pid file directories (Issue #545).
  Contributed by Chris Streeter.

2.4.3

release-date  2011-11-22 06:00 p.m. GMT
release-by   Ask Solem

• Fixes module import typo in celeryctl (Issue #538).
  Fix contributed by Chris Streeter.
2.4.2

release-date 2011-11-14 12:00 p.m. GMT
release-by Ask Solem

- Program module no longer uses relative imports so that it’s possible to do `python -m celery.bin.name`.

2.4.1

release-date 2011-11-07 06:00 p.m. GMT
release-by Ask Solem

- `celeryctl inspect` commands was missing output.
- processes pool: Decrease polling interval for less idle CPU usage.
- processes pool: `MaybeEncodingError` wasn’t wrapped in `ExceptionInfo` (Issue #524).
- worker: would silence errors occurring after task consumer started.
- logging: Fixed a bug where unicode in stdout redirected log messages couldn’t be written (Issue #522).

2.4.0

release-date 2011-11-04 04:00 p.m. GMT
release-by Ask Solem

Important Notes

- Now supports Python 3.
- Fixed deadlock in worker process handling (Issue #496).

  A deadlock could occur after spawning new child processes because the logging library’s mutex wasn’t properly reset after fork.

  The symptoms of this bug affecting would be that the worker simply stops processing tasks, as none of the workers child processes are functioning. There was a greater chance of this bug occurring with `maxtasksperchild` or a time-limit enabled.

  This is a workaround for [http://bugs.python.org/issue6721#msg140215](http://bugs.python.org/issue6721#msg140215).

  Be aware that while this fixes the logging library lock, there could still be other locks initialized in the parent process, introduced by custom code.

  Fix contributed by Harm Verhagen.
- AMQP Result backend: Now expires results by default.

  The default expiration value is now taken from the `CELERY_TASK_RESULT_EXPIRES` setting.

  The old `CELERY_AMQP_TASK_RESULT_EXPIRES` setting has been deprecated and will be removed in version 4.0.

  Note that this means that the result backend requires RabbitMQ 2.1.0 or higher, and that you have to disable expiration if you’re running with an older version. You can do so by disabling the `CELERY_TASK_RESULT_EXPIRES` setting:
Eventlet: Fixed problem with shutdown (Issue #457).

Broker transports can be now be specified using URLs

The broker can now be specified as a URL instead. This URL must have the format:

```
transport://user:password@hostname:port/virtual_host
```

for example the default broker is written as:

```
amqp://guest:guest@localhost:5672//
```

The scheme is required, so that the host is identified as a URL and not just a host name. User, password, port and virtual_host are optional and defaults to the particular transports default value.

**Note:** Note that the path component (virtual_host) always starts with a forward-slash. This is necessary to distinguish between the virtual host '' (empty) and '/', which are both acceptable virtual host names.

A virtual host of '/' becomes:

```
amqp://guest:guest@localhost:5672//
```

and a virtual host of '' (empty) becomes:

```
amqp://guest:guest@localhost:5672/
```

So the leading slash in the path component is **always required**.

In addition the BROKER_URL setting has been added as an alias to BROKER_HOST. Any broker setting specified in both the URL and in the configuration will be ignored, if a setting isn’t provided in the URL then the value from the configuration will be used as default.

Also, programs now support the **--broker** option to specify a broker URL on the command-line:

```
$ celery worker -b redis://localhost
$ celery inspect -b amqp://guest:guest@localhost://e
```

The environment variable CELERY_BROKER_URL can also be used to easily override the default broker used.

- The deprecated celery.loaders.setup_loader() function has been removed.
- The CELERY_TASK_ERROR_WHITELIST setting has been replaced by a more flexible approach (Issue #447).

The error mail sending logic is now available as Task.ErrorMail, with the implementation (for reference) in celery.utils.mail.

The error mail class can be sub-classed to gain complete control of when error messages are sent, thus removing the need for a separate white-list setting.

The CELERY_TASK_ERROR_WHITELIST setting has been deprecated, and will be removed completely in version 4.0.

- Additional Deprecations
The following functions has been deprecated and is scheduled for removal in version 4.0:

<table>
<thead>
<tr>
<th>Old function</th>
<th>Alternative</th>
</tr>
</thead>
<tbody>
<tr>
<td>celery.loaders.current_loader</td>
<td>celery.current_app.loader</td>
</tr>
<tr>
<td>celery.loaders.load_settings</td>
<td>celery.current_app.conf</td>
</tr>
<tr>
<td>celery.execute.apply</td>
<td>Task.apply</td>
</tr>
<tr>
<td>celery.execute.apply_async</td>
<td>Task.apply_async</td>
</tr>
<tr>
<td>celery.execute.delay_task</td>
<td>celery.execute.send_task</td>
</tr>
</tbody>
</table>

The following settings has been deprecated and is scheduled for removal in version 4.0:

<table>
<thead>
<tr>
<th>Old setting</th>
<th>Alternative</th>
</tr>
</thead>
<tbody>
<tr>
<td>CELERYD_LOG_LEVEL</td>
<td>celery worker --loglevel=</td>
</tr>
<tr>
<td>CELERYD_LOG_FILE</td>
<td>celery worker --logfile=</td>
</tr>
<tr>
<td>CELERYBEAT_LOG_LEVEL</td>
<td>celery beat --loglevel=</td>
</tr>
<tr>
<td>CELERYBEAT_LOG_FILE</td>
<td>celery beat --logfile=</td>
</tr>
<tr>
<td>CELERYMON_LOG_LEVEL</td>
<td>celerymon --loglevel=</td>
</tr>
<tr>
<td>CELERYMON_LOG_FILE</td>
<td>celerymon --logfile=</td>
</tr>
</tbody>
</table>

News

- No longer depends on pyparsing.
- Now depends on Kombu 1.4.3.
- CELERY_IMPORTS can now be a scalar value (Issue #485).
  It’s too easy to forget to add the comma after the sole element of a tuple, and this is something that often affects newcomers.
  The docs should probably use a list in examples, as using a tuple for this doesn’t even make sense. Nonetheless, there are many tutorials out there using a tuple, and this change should be a help to new users.
  Suggested by @jsaxon-cars.
- Fixed a memory leak when using the thread pool (Issue #486).
  Contributed by Kornelijus Survila.
- The statedb wasn’t saved at exit.
  This has now been fixed and it should again remember previously revoked tasks when a --statedb is enabled.
- Adds EMAIL_USE_TLS to enable secure SMTP connections (Issue #418).
  Contributed by Stefan Kjartansson.
- Now handles missing fields in task messages as documented in the message format documentation.
  - Missing required field throws InvalidTaskError
  - Missing args/kwargs is assumed empty.
  Contributed by Chris Chamberlin.
- Fixed race condition in celery.events.state (celerymon/celeryev) where task info would be removed while iterating over it (Issue #501).
• The Cache, Cassandra, MongoDB, Redis and Tyrant backends now respects the `CELERY_RESULT_SERIALIZER` setting (Issue #435).

  This means that only the database (Django/SQLAlchemy) backends currently doesn’t support using custom serializers.

  Contributed by Steeve Morin

• Logging calls no longer manually formats messages, but delegates that to the logging system, so tools like Sentry can easier work with the messages (Issue #445).

  Contributed by Chris Adams.

• `multi` now supports a `stop_verify` command to wait for processes to shutdown.

• Cache backend didn’t work if the cache key was unicode (Issue #504).

  Fix contributed by Neil Chintomby.

• New setting `CELERY_RESULT_DB_SHORT_LIVED_SESSIONS` added, which if enabled will disable the caching of SQLAlchemy sessions (Issue #449).

  Contributed by Leo Dirac.

• All result backends now implements `__reduce__` so that they can be pickled (Issue #441).

  Fix contributed by Remy Noel

• multi didn’t work on Windows (Issue #472).

• New-style `CELERY_REDIS_*` settings now takes precedence over the old `REDIS_*` configuration keys (Issue #508).

  Fix contributed by Joshua Ginsberg

• Generic beat init-script no longer sets `bash -e` (Issue #510).

  Fix contributed by Roger Hu.

• Documented that Chords don’t work well with `redis-server` versions before 2.2.

  Contributed by Dan McGee.

• The `CELERYBEAT_MAX_LOOP_INTERVAL` setting wasn’t respected.

• `inspect.registered_tasks` renamed to `inspect.registered` for naming consistency.

  The previous name is still available as an alias.

  Contributed by Mher Movsisyan

• Worker logged the string representation of args and kwargs without safe guards (Issue #480).

• RHEL init-script: Changed worker start-up priority.

  The default start / stop priorities for MySQL on RHEL are:

  ```
  # chkconfig: - 64 36
  ```

  Therefore, if Celery is using a database as a broker / message store, it should be started after the database is up and running, otherwise errors will ensue. This commit changes the priority in the init-script to:

  ```
  # chkconfig: - 85 15
  ```
which are the default recommended settings for 3-rd party applications and assure that Celery will be started after the database service & shut down before it terminates.

Contributed by Yury V. Zaytsev.

- **KeyValueStoreBackend.get_many** didn’t respect the *timeout* argument (Issue #512).
- **beat/events**’s *--workdir* option didn’t *chdir(2)* before after configuration was attempted (Issue #506).
- After deprecating 2.4 support we can now name modules correctly, since we can take use of absolute imports.

Therefore the following internal modules have been renamed:

- `celery.concurrency.evlet` -> `celery.concurrency.eventlet`
- `celery.concurrency.evg` -> `celery.concurrency.gevent`

- **AUTHORS** file is now sorted alphabetically.

Also, as you may have noticed the contributors of new features/fixes are now mentioned in the Changelog.

### 3.13.14 Change history for Celery 2.3

- **2.3.4**
  - **Security Fixes**
  - **Fixes**
- **2.3.3**
- **2.3.2**
  - **News**
  - **Fixes**
- **2.3.1**
  - **Fixes**
- **2.3.0**
  - **Important Notes**
  - **News**
  - **Fixes**

#### 2.3.4

- **release-date** 2011-11-25 04:00 p.m. GMT
- **release-by** Ask Solem

**Security Fixes**

- [Security: CELERYSA-0001] Daemons would set effective id’s rather than real id’s when the *--uid* / *--gid* arguments to `celery multi,celeryd_detach,celery beat` and `celery events` were used.
This means privileges weren’t properly dropped, and that it would be possible to regain supervisor privileges later.

**Fixes**

- Backported fix for #455 from 2.4 to 2.3.
- StateDB wasn’t saved at shutdown.
- Fixes worker sometimes hanging when hard time limit exceeded.

### 2.3.3

**release-date** 2011-16-09 05:00 p.m. BST  
**release-by** Mher Movsisyan

- Monkey patching `sys.stdout` could result in the worker crashing if the replacing object didn’t define `isatty()` (Issue #477).
- `CELERYD` option in `/etc/default/celeryd` shouldn’t be used with generic init-scripts.

### 2.3.2

**release-date** 2011-10-07 05:00 p.m. BST  
**release-by** Ask Solem

**News**

- Improved Contributing guide.  
  If you’d like to contribute to Celery you should read the *Contributing Guide*.  
  We’re looking for contributors at all skill levels, so don’t hesitate!
- Now depends on Kombu 1.3.1
- `Task.request` now contains the current worker host name (Issue #460).  
  Available as `task.request.hostname`.
- It's now easier for app subclasses to extend how they're pickled. (see `celery.app.AppPickler`).

**Fixes**

- `purge/discard_all` wasn’t working correctly (Issue #455).
- The coloring of log messages didn’t handle non-ASCII data well (Issue #427).
- [Windows] the multiprocessing pool tried to import `os.kill` even though this isn’t available there (Issue #450).
- Fixes case where the worker could become unresponsive because of tasks exceeding the hard time limit.
- The `task-sent` event was missing from the event reference.
- `ResultSet.iterate` now returns results as they finish (Issue #459).
This wasn’t the case previously, even though the documentation states this was the expected behavior.

- Retrieval will no longer be performed when tasks are called directly (using `__call__`). Instead the exception passed to `retry` will be re-raised.
- Eventlet no longer crashes if autoscale is enabled.
- Growing and shrinking eventlet pools is still not supported.
- `py24` target removed from `tox.ini`.

### 2.3.1

**release-date** 2011-08-07 08:00 p.m. BST  
**release-by** Ask Solem

### Fixes

- The `CELERY_AMQP_TASK_RESULT_EXPIRES` setting didn’t work, resulting in an AMQP related error about not being able to serialize floats while trying to publish task states (Issue #446).

### 2.3.0

**release-date** 2011-08-05 12:00 p.m. BST  
**tested** CPython: 2.5, 2.6, 2.7; PyPy: 1.5; Jython: 2.5.2  
**release-by** Ask Solem

### Important Notes

- Now requires Kombu 1.2.1
- Results are now disabled by default.

  The AMQP backend wasn’t a good default because often the users were not consuming the results, resulting in thousands of queues.

  While the queues can be configured to expire if left unused, it wasn’t possible to enable this by default because this was only available in recent RabbitMQ versions (2.1.1+)

  With this change enabling a result backend will be a conscious choice, which will hopefully lead the user to read the documentation and be aware of any common pitfalls with the particular backend.

  The default backend is now a dummy backend (`celery.backends.base.DisabledBackend`). Saving state is simply an no-op, and `AsyncResult.wait()`, `.result`, `.state`, etc. will raise a `NotImplementedError` telling the user to configure the result backend.

  For help choosing a backend please see `Result Backends`.

  If you depend on the previous default which was the AMQP backend, then you have to set this explicitly before upgrading:

  ```
  CELERY_RESULT_BACKEND = 'amqp'
  ```
Note: For django-celery users the default backend is still database, and results are not disabled by default.

- The Debian init-scripts have been deprecated in favor of the generic-init.d init-scripts.
  In addition generic init-scripts for celerybeat and celeryev has been added.

News

- Automatic connection pool support.
  The pool is used by everything that requires a broker connection, for example calling tasks, sending broadcast commands, retrieving results with the AMQP result backend, and so on.
  The pool is disabled by default, but you can enable it by configuring the BROKER_POOL_LIMIT setting:

  ```python
  BROKER_POOL_LIMIT = 10
  ```
  A limit of 10 means a maximum of 10 simultaneous connections can co-exist. Only a single connection will ever be used in a single-thread environment, but in a concurrent environment (threads, greenlets, etc., but not processes) when the limit has been exceeded, any try to acquire a connection will block the thread and wait for a connection to be released. This is something to take into consideration when choosing a limit.
  A limit of None or 0 means no limit, and connections will be established and closed every time.

- Introducing Chords (taskset callbacks).
  A chord is a task that only executes after all of the tasks in a taskset has finished executing. It’s a fancy term for “taskset callbacks” adopted from C\omega).
  It works with all result backends, but the best implementation is currently provided by the Redis result backend.
  Here’s an example chord:

  ```python
  >>> chord(add.subtask((i, i))
    ... for i in xrange(100))(tsum.subtask()).get()
  9900
  ```
  Please read the Chords section in the user guide, if you want to know more.

- Time limits can now be set for individual tasks.
  To set the soft and hard time limits for a task use the time_limit and soft_time_limit attributes:

  ```python
  import time
  @task(time_limit=60, soft_time_limit=30)
  def sleeptask(seconds):
    time.sleep(seconds)
  ```
  If the attributes are not set, then the workers default time limits will be used.

  New in this version you can also change the time limits for a task at runtime using the time_limit() remote control command:
```python
>>> from celery.task import control
>>> control.time_limit('tasks.sleeptask',
...     soft=60, hard=120, reply=True)
[['worker1.example.com': {'ok': 'time limits set successfully'}}]
```

Only tasks that starts executing after the time limit change will be affected.

**Note:** Soft time limits will still not work on Windows or other platforms that don’t have the SIGUSR1 signal.

- **Redis backend configuration directive names changed to include the `CELERY_` prefix.**

<table>
<thead>
<tr>
<th>Old setting name</th>
<th>Replace with</th>
</tr>
</thead>
<tbody>
<tr>
<td>REDIS_HOST</td>
<td>CELERY_REDIS_HOST</td>
</tr>
<tr>
<td>REDIS_PORT</td>
<td>CELERY_REDIS_PORT</td>
</tr>
<tr>
<td>REDIS_DB</td>
<td>CELERY_REDIS_DB</td>
</tr>
<tr>
<td>REDIS_PASSWORD</td>
<td>CELERY_REDIS_PASSWORD</td>
</tr>
</tbody>
</table>

The old names are still supported but pending deprecation.
- **PyPy:** The default pool implementation used is now multiprocessing if running on PyPy 1.5.
- **multi:** now supports “pass through” options.
  
  Pass through options makes it easier to use Celery without a configuration file, or just add last-minute options on the command line.
  
  Example use:

```bash
$ celery multi start 4 -c 2 -- broker.host=amqp.example.com \
    broker.vhost=/ \
    celery.disable_rate_limits=yes
```

- **celerybeat:** Now retries establishing the connection (Issue #419).
- **celeryctl:** New `list bindings` command.
  
  Lists the current or all available bindings, depending on the broker transport used.
- **Heartbeat is now sent every 30 seconds (previously every 2 minutes).**
- **ResultSet.join_native()** and **iter_native()** is now supported by the Redis and Cache result backends.
  
  This is an optimized version of `join()` using the underlying backends ability to fetch multiple results at once.
- **Can now use SSL when sending error e-mails by enabling the `EMAIL_USE_SSL` setting.**
- **events.default_dispatcher():** Context manager to easily obtain an event dispatcher instance using the connection pool.
- **Import errors in the configuration module won’t be silenced anymore.**
- **ResultSet.iterate:** Now supports the `timeout`, `propagate` and `interval` arguments.
- **with_default_connection -> with default_connection**
- **TaskPool.apply_async:** Keyword arguments `callbacks` and `errbacks` has been renamed to `callback` and `errback` and take a single scalar value instead of a list.
• No longer propagates errors occurring during process cleanup (Issue #365)
• Added TaskSetResult.delete(), which will delete a previously saved taskset result.
• celerybeat now syncs every 3 minutes instead of only at shutdown (Issue #382).
• Monitors now properly handles unknown events, so user-defined events are displayed.
• Terminating a task on Windows now also terminates all of the tasks child processes (Issue #384).
• worker: -I|--include option now always searches the current directory to import the specified modules.
• Cassandra backend: Now expires results by using TTLs.
• Functional test suite in funtests is now actually working properly, and passing tests.

Fixes

• celeryev was trying to create the pidfile twice.
• celery.contrib.batches: Fixed problem where tasks failed silently (Issue #393).
• Fixed an issue where logging objects would give “<Unrepresentable”, even though the objects were.
• CELERY_TASK_ERROR_WHITE_LIST is now properly initialized in all loaders.
• celeryd_detach now passes through command line configuration.
• Remote control command add_consumer now does nothing if the queue is already being consumed from.

3.13.15 Change history for Celery 2.2

• 2.2.8
  – Security Fixes
• 2.2.7
• 2.2.6
  – Important Notes
  – Fixes
• 2.2.5
  – Important Notes
  – News
  – Fixes
• 2.2.4
  – Fixes
• 2.2.3
  – Fixes
• 2.2.2
  – Fixes
Security Fixes

• [Security: CELERYSA-0001] Daemons would set effective id’s rather than real id’s when the --uid/--gid arguments to celery multi, celeryd_detach, celery beat and celery events were used. This means privileges weren’t properly dropped, and that it would be possible to regain supervisor privileges later.

2.2.7

release-date 2011-06-13 04:00 p.m. BST
release-by Ask Solem

• New signals: after_setup_logger and after_setup_task_logger

These signals can be used to augment logging configuration after Celery has set up logging.
• Redis result backend now works with Redis 2.4.4.
• multi: The --gid option now works correctly.
• worker: Retry wrongfully used the repr of the traceback instead of the string representation.
• App.config_from_object: Now loads module, not attribute of module.
• Fixed issue where logging of objects would give “<Unrepresentable: ...>”
Important Notes

- Now depends on Kombu 1.1.2.
- Dependency lists now explicitly specifies that we don’t want python-dateutil 2.x, as this version only supports Python 3.

If you have installed dateutil 2.0 by accident you should downgrade to the 1.5.0 version:

```
$ pip install -U python-dateutil==1.5.0
```

or by easy_install:

```
$ easy_install -U python-dateutil==1.5.0
```

Fixes

- The new WatchedFileHandler broke Python 2.5 support (Issue #367).
- Task: Don’t use app.main if the task name is set explicitly.
- Sending emails didn’t work on Python 2.5, due to a bug in the version detection code (Issue #378).
- Beat: Adds method ScheduleEntry._default_now
  
  This method can be overridden to change the default value of last_run_at.
- An error occurring in process cleanup could mask task errors.
  
  We no longer propagate errors happening at process cleanup, but log them instead. This way they won’t interfere with publishing the task result (Issue #365).
- Defining tasks didn’t work properly when using the Django shell_plus utility (Issue #366).
-AsyncResult.get didn’t accept the interval and propagate arguments.
- worker: Fixed a bug where the worker wouldn’t shutdown if a socket.error was raised.

2.2.5

release-date 2011-03-28 06:00 p.m. CEST
release-by Ask Solem

Important Notes

- Now depends on Kombu 1.0.7

News

- Our documentation is now hosted by Read The Docs (http://docs.celeryproject.org), and all links have been changed to point to the new URL.
- Logging: Now supports log rotation using external tools like logrotate.d (Issue #321)

  This is accomplished by using the WatchedFileHandler, which re-opens the file if it’s renamed or deleted.
• **otherqueues tutorial now documents how to configure Redis/Database result** backends.
• gevent: Now supports ETA tasks.
  
  But gevent still needs `CELERY_DISABLE_RATE_LIMITS=True` to work.
• TaskSet User Guide: now contains TaskSet callback recipes.
• Eventlet: New signals:
  
  ```
  - eventlet_pool_started
  - eventlet_pool_preshutdown
  - eventlet_pool_postshutdown
  - eventlet_pool_apply
  ```

  See `celery.signals` for more information.
• New `BROKER_TRANSPORT_OPTIONS` setting can be used to pass additional arguments to a particular broker transport.
• worker: `worker_pid` is now part of the request info as returned by broadcast commands.
• TaskSet.apply/Taskset.apply_async now accepts an optional `taskset_id` argument.
• The `taskset_id` (if any) is now available in the Task request context.
• SQLAlchemy result backend: `taskset_id` and `taskset_id` columns now have a unique constraint (tables need to recreated for this to take affect).
• Task user guide: Added section about choosing a result backend.
• Removed unused attribute `AsyncResult.uuid`.

**Fixes**

• multiprocessing.Pool: Fixes race condition when marking job with `WorkerLostError` (Issue #268).
  
  The process may have published a result before it was terminated, but we have no reliable way to detect that this is the case.
  
  So we have to wait for 10 seconds before marking the result with `WorkerLostError`. This gives the result handler a chance to retrieve the result.
• multiprocessing.Pool: Shutdown could hang if rate limits disabled.
  
  There was a race condition when the MainThread was waiting for the pool semaphore to be released. The ResultHandler now terminates after 5 seconds if there are unacked jobs, but no worker processes left to start them (it needs to timeout because there could still be an ack+result that we haven’t consumed from the result queue. It is unlikely we’ll receive any after 5 seconds with no worker processes).
• `celerybeat`: Now creates pidfile even if the `--detach` option isn’t set.
• eventlet/gevent: The broadcast command consumer is now running in a separate green-thread.
  
  This ensures broadcast commands will take priority even if there are many active tasks.
• Internal module `celery.worker.controllers` renamed to `celery.worker.mediator`.
• worker: Threads now terminates the program by calling `os._exit`, as it is the only way to ensure exit in the case of syntax errors, or other unrecoverable errors.
• Fixed typo in `maybe_timedelta` (Issue #352).
• worker: Broadcast commands now logs with loglevel debug instead of warning.
• AMQP Result Backend: Now resets cached channel if the connection is lost.
• Polling results with the AMQP result backend wasn’t working properly.
• Rate limits: No longer sleeps if there are no tasks, but rather waits for the task received condition (Performance improvement).
• ConfigurationView: `iter(dict)` should return keys, not items (Issue #362).
• celerybeat: `PersistentScheduler` now automatically removes a corrupted schedule file (Issue #346).
• Programs that doesn’t support positional command-line arguments now provides a user friendly error message.
• Programs no longer tries to load the configuration file when showing `--version` (Issue #347).
• Autoscaler: The “all processes busy” log message is now severity debug instead of error.
• worker: If the message body can’t be decoded, it’s now passed through `safe_str` when logging.
  
  This to ensure we don’t get additional decoding errors when trying to log the failure.
• `app.config_from_object/app.config_from_envvar` now works for all loaders.
• Now emits a user-friendly error message if the result backend name is unknown (Issue #349).
• celery.contrib.batches: Now sets loglevel andlogfile in the task request so `task.get_logger` works with batch tasks (Issue #357).
• worker: An exception was raised if using the amqp transport and the prefetch count value exceeded 65535 (Issue #359).
  
  The prefetch count is incremented for every received task with an ETA/countdown defined. The prefetch count is a short, so can only support a maximum value of 65535. If the value exceeds the maximum value we now disable the prefetch count, it’s re-enabled as soon as the value is below the limit again.
• `cursesmon`: Fixed unbound local error (Issue #303).
• eventlet/gevent is now imported on demand so autodoc can import the modules without having eventlet/gevent installed.
• worker: Ack callback now properly handles `AttributeError`.
• Task.after_return is now always called after the result has been written.
• Cassandra Result Backend: Should now work with the latest `pycassa` version.
• multiprocessing.Pool: No longer cares if the putlock semaphore is released too many times (this can happen if one or more worker processes are killed).
• SQLAlchemy Result Backend: Now returns accidentally removed `date_done` again (Issue #325).
• Task.request context is now always initialized to ensure calling the task function directly works even if it actively uses the request context.
• Exception occurring when iterating over the result from `TaskSet.apply` fixed.
• eventlet: Now properly schedules tasks with an ETA in the past.

2.2.4

release-date 2011-02-19 00:00 AM CET
release-by Ask Solem
Fixes

- worker: 2.2.3 broke error logging, resulting in tracebacks not being logged.
- AMQP result backend: Polling task states didn’t work properly if there were more than one result message in the queue.
- `TaskSet.apply_async()` and `TaskSet.apply()` now supports an optional `taskset_id` keyword argument (Issue #331).
- The current taskset id (if any) is now available in the task context as `request.taskset` (Issue #329).
- SQLAlchemy result backend: `date_done` was no longer part of the results as it had been accidentally removed. It’s now available again (Issue #325).
- SQLAlchemy result backend: Added unique constraint on `Task.id` and `TaskSet.taskset_id`. Tables needs to be recreated for this to take effect.
- Fixed exception raised when iterating on the result of `TaskSet.apply()`.
- Tasks user guide: Added section on choosing a result backend.

2.2.3

**release-date** 2011-02-12 04:00 p.m. CET

**release-by** Ask Solem

Fixes

- Now depends on Kombu 1.0.3
- `Task.retry` now supports a `max_retries` argument, used to change the default value.
- `multiprocessing.cpu_count` may raise `NotImplementedError` on platforms where this isn’t supported (Issue #320).
- Coloring of log messages broke if the logged object wasn’t a string.
- Fixed several typos in the init-script documentation.
- A regression caused `Task.exchange` and `Task.routing_key` to no longer have any effect. This is now fixed.
- Routing user guide: Fixes typo, routers in `CELERY_ROUTES` must be instances, not classes.
- `celeryev` didn’t create pidfile even though the `--pidfile` argument was set.
- Task logger format was no longer used (Issue #317).
  
  The id and name of the task is now part of the log message again.

- A safe version of `repr()` is now used in strategic places to ensure objects with a broken `__repr__` doesn’t crash the worker, or otherwise make errors hard to understand (Issue #298).
- Remote control command `active_queues`: didn’t account for queues added at runtime.
  
  In addition the dictionary replied by this command now has a different structure: the exchange key is now a dictionary containing the exchange declaration in full.

- The `celery worker -Q` option removed unused queue declarations, so routing of tasks could fail.
Queues are no longer removed, but rather `app.amqp.queues.consume_from()` is used as the list of queues to consume from.

This ensures all queues are available for routing purposes.

- **celeryctl**: Now supports the `inspect active_queues` command.

### 2.2.2

**release-date** 2011-02-03 04:00 p.m. CET

**release-by** Ask Solem

**Fixes**

- `celerybeat` couldn’t read the schedule properly, so entries in `CELERYBEAT_SCHEDULE` wouldn’t be scheduled.
- Task error log message now includes `exc_info` again.
- The `eta` argument can now be used with `task.retry`.
  
  Previously it was overwritten by the countdown argument.
- `celery multi/celeryd_detach`: Now logs errors occurring when executing the `celery worker` command.
- `daemonizing tutorial`: Fixed typo `--time-limit 300 -> --time-limit=300`
- Colors in logging broke non-string objects in log messages.
- `setup_task_logger` no longer makes assumptions about magic task kwargs.

### 2.2.1

**release-date** 2011-02-02 04:00 p.m. CET

**release-by** Ask Solem

**Fixes**

- Eventlet pool was leaking memory (Issue #308).
- Deprecated function `celery.execute.delay_task` was accidentally removed, now available again.
- `BasePool.on_terminate` stub didn’t exist
- `celeryd_detach`: Adds readable error messages if user/group name doesn’t exist.
- Smarter handling of unicode decode errors when logging errors.

### 2.2.0

**release-date** 2011-02-01 10:00 AM CET

**release-by** Ask Solem

---

3.13. History
Important Notes

- Carrot has been replaced with Kombu

  Kombu is the next generation messaging library for Python, fixing several flaws present in Carrot that was hard to fix without breaking backwards compatibility.

  Also it adds:
  - First-class support for virtual transports; Redis, Django ORM, SQLAlchemy, Beanstalk, MongoDB, CouchDB and in-memory.
  - Consistent error handling with introspection,
  - The ability to ensure that an operation is performed by gracefully handling connection and channel errors,
  - Message compression (zlib, bz2, or custom compression schemes).

  This means that ghettoq is no longer needed as the functionality it provided is already available in Celery by default. The virtual transports are also more feature complete with support for exchanges (direct and topic). The Redis transport even supports fanout exchanges so it’s able to perform worker remote control commands.

- Magic keyword arguments pending deprecation.

  The magic keyword arguments were responsible for many problems and quirks: notably issues with tasks and decorators, and name collisions in keyword arguments for the unaware.

  It wasn’t easy to find a way to deprecate the magic keyword arguments, but we think this is a solution that makes sense and it won’t have any adverse effects for existing code.

  The path to a magic keyword argument free world is:
  - the celery.decorators module is deprecated and the decorators can now be found in celery.task.
  - The decorators in celery.task disables keyword arguments by default
  - All examples in the documentation have been changed to use celery.task.

  This means that the following will have magic keyword arguments enabled (old style):

  ```python
  from celery.decorators import task
  @task()
  def add(x, y, **kwargs):
      print('In task %s' % kwargs['task_id'])
      return x + y
  ```

  And this won’t use magic keyword arguments (new style):

  ```python
  from celery.task import task
  @task()
  def add(x, y):
      print('In task %s' % add.request.id)
      return x + y
  ```

  In addition, tasks can choose not to accept magic keyword arguments by setting the task.accept_magic_kwargs attribute.
Deprecation

Using the decorators in `celery.decorators` emits a `PendingDeprecationWarning` with a helpful message urging you to change your code, in version 2.4 this will be replaced with a `DeprecationWarning`, and in version 4.0 the `celery.decorators` module will be removed and no longer exist.

Similarly, the `task.accept_magic_kwargs` attribute will no longer have any effect starting from version 4.0.

• The magic keyword arguments are now available as `task.request`

  This is called the context. Using thread-local storage the context contains state that’s related to the current request.

  It’s mutable and you can add custom attributes that’ll only be seen by the current task request.

  The following context attributes are always available:

<table>
<thead>
<tr>
<th>Magic Keyword Argument</th>
<th>Replace with</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>kwarg['task_id']</code></td>
<td><code>self.request.id</code></td>
</tr>
<tr>
<td><code>kwarg['delivery_info']</code></td>
<td><code>self.request.delivery_info</code></td>
</tr>
<tr>
<td><code>kwarg['task_retries']</code></td>
<td><code>self.request.retries</code></td>
</tr>
<tr>
<td><code>kwarg['logfile']</code></td>
<td><code>self.requestlogfile</code></td>
</tr>
<tr>
<td><code>kwarg['loglevel']</code></td>
<td><code>self.request.loglevel</code></td>
</tr>
<tr>
<td><code>kwarg['task_is_eager']</code></td>
<td><code>self.request.is_eager</code></td>
</tr>
<tr>
<td><strong>NEW</strong></td>
<td><code>self.request.args</code></td>
</tr>
<tr>
<td><strong>NEW</strong></td>
<td><code>self.request.kwargs</code></td>
</tr>
</tbody>
</table>

  In addition, the following methods now automatically uses the current context, so you don’t have to pass `kwargs` manually anymore:

  - `task.retry`
  - `task.get_logger`
  - `task.update_state`

• Eventlet support.

  This is great news for I/O-bound tasks!

  To change pool implementations you use the `celery worker --pool` argument, or globally using the `CELYRD_POOL` setting. This can be the full name of a class, or one of the following aliases: `processes`, `eventlet`, `gevent`.

  For more information please see the `Concurrency with Eventlet` section in the User Guide.

Why not gevent?

For our first alternative concurrency implementation we’ve focused on Eventlet, but there’s also an experimental `gevent` pool available. This is missing some features, notably the ability to schedule ETA tasks.

Hopefully the `gevent` support will be feature complete by version 2.3, but this depends on user demand (and contributions).

• Python 2.4 support deprecated!
We’re happy to announce that this is the last version to support Python 2.4.

You’re urged to make some noise if you’re currently stuck with Python 2.4. Complain to your package maintainers, sysadmins and bosses: tell them it’s time to move on!

Apart from wanting to take advantage of `with` statements, coroutines, conditional expressions and enhanced `try` blocks, the code base now contains so many 2.4 related hacks and workarounds it’s no longer just a compromise, but a sacrifice.

If it really isn’t your choice, and you don’t have the option to upgrade to a newer version of Python, you can just continue to use Celery 2.2. Important fixes can be back ported for as long as there’s interest.

• worker: Now supports Autoscaling of child worker processes.

The `--autoscale` option can be used to configure the minimum and maximum number of child worker processes:

```
--autoscale=AUTOSCALE
  Enable autoscaling by providing max_concurrency, min_concurrency. Example:
  --autoscale=10,3 (always keep 3 processes, but grow to 10 if necessary).
```

• Remote Debugging of Tasks

celery.contrib.rdb is an extended version of pdb that enables remote debugging of processes that doesn’t have terminal access.

Example usage:

```
from celery.contrib import rdb
from celery.task import task

@task()
def add(x, y):
    result = x + y
    # set breakpoint
    rdb.set_trace()
    return result

@func:`~celery.contrib.rdb.set_trace` sets a breakpoint at the current location and creates a socket you can telnet into to remotely debug your task.

The debugger may be started by multiple processes at the same time, so rather than using a fixed port the debugger will search for an available port, starting from the base port (6900 by default). The base port can be changed using the environment variable :envvar:`CELERY_RDB_PORT`.

By default the debugger will only be available from the local host, to enable access from the outside you have to set the environment variable :envvar:`CELERY_RDB_HOST`.

When the worker encounters your breakpoint it will log the following information:

```
[INFO/MainProcess] Received task:
  tasks.add[d7261c71-4962-47e5-b342-2448bedd20e8]
```

(continues on next page)
If you telnet the port specified you'll be presented with a `pdb` shell:

```console
$ telnet localhost 6900
Connected to localhost.
Escape character is '^]'.
> /opt/devel/demoapp/tasks.py(128)add()
--> return result
(Pdb)
```
Enter ```help``` to get a list of available commands,
It may be a good idea to read the `Python Debugger Manual` if you have never used `pdb` before.

- Events are now transient and is using a topic exchange (instead of direct).

The `CELERYD_EVENT_EXCHANGE`, `CELERYD_EVENT_ROUTING_KEY`, `CELERYD_EVENT_EXCHANGE_TYPE` settings are no longer in use.

This means events won’t be stored until there’s a consumer, and the events will be gone as soon as the consumer stops. Also it means there can be multiple monitors running at the same time.

The routing key of an event is the type of event (e.g., `worker.started`, `worker.heartbeat`, `task.succeeded`, etc). This means a consumer can filter on specific types, to only be alerted of the events it cares about.

Each consumer will create a unique queue, meaning it’s in effect a broadcast exchange.

This opens up a lot of possibilities, for example the workers could listen for worker events to know what workers are in the neighborhood, and even restart workers when they go down (or use this information to optimize tasks/autoscaling).

**Note:** The event exchange has been renamed from "celeryevent" to "celeryev" so it doesn’t collide with older versions.

If you’d like to remove the old exchange you can do so by executing the following command:

```console
$ camqadm exchange.delete celeryevent
```

- The worker now starts without configuration, and configuration can be specified directly on the command-line.

  Configuration options must appear after the last argument, separated by two dashes:

  ```bash
  $ celery worker -l info -I tasks -- broker.host=localhost broker.vhost=/app
  ```

- Configuration is now an alias to the original configuration, so changes to the original will reflect Celery at runtime.

- `celery.conf` has been deprecated, and modifying `celery.conf.ALWAYS_EAGER` will no longer have any effect.
The default configuration is now available in the `celery.app.defaults` module. The available configuration options and their types can now be introspected.

- Remote control commands are now provided by `kombu.pidbox`, the generic process mailbox.
- Internal module `celery.worker.listener` has been renamed to `celery.worker.consumer`, and `.CarrotListener` is now `.Consumer`.
- Previously deprecated modules `celery.models` and `celery.management.commands` have now been removed as per the deprecation time-line.

  Executing arbitrary code using pickle is a potential security issue if someone gains unrestricted access to the message broker.

  If you really need this functionality, then you’d’ve to add this to your own project.

- **[Security: Low severity]** The `stats` command no longer transmits the broker password.

  One would’ve needed an authenticated broker connection to receive this password in the first place, but sniffing the password at the wire level would’ve been possible if using unencrypted communication.

### News

- The internal module `celery.task.builtins` has been removed.
- The module `celery.task.schedules` is deprecated, and `celery.schedules` should be used instead.

  For example if you have:

  ```python
  from celery.task.schedules import crontab
  ```

  You should replace that with:

  ```python
  from celery.schedules import crontab
  ```

  The module needs to be renamed because it must be possible to import schedules without importing the `celery.task` module.

- The following functions have been deprecated and is scheduled for removal in version 2.3:

  - `celery.execute.apply_async`
    Use `task.apply_async()` instead.

  - `celery.execute.apply`
    Use `task.apply()` instead.

  - `celery.execute.delay_task`
    Use `registry.tasks[name].delay()` instead.

- Importing `TaskSet` from `celery.task.base` is now deprecated.

  You should use:

  ```python
  >>> from celery.task import TaskSet
  ```

  instead.
• New remote control commands:
  
  – *active_queues*

  Returns the queue declarations a worker is currently consuming from.

• Added the ability to retry publishing the task message in the event of connection loss or failure.

  This is disabled by default but can be enabled using the `CELERY_TASK_PUBLISH_RETRY` setting, and tweaked by the `CELERY_TASK_PUBLISH_RETRY_POLICY` setting.

  In addition `retry`, and `retry_policy` keyword arguments have been added to `Task.apply_async`.

  **Note:** Using the `retry` argument to `apply_async` requires you to handle the publisher/connection manually.

• Periodic Task classes (`@periodic_task/PeriodicTask`) will *not* be deprecated as previously indicated in the source code.

  But you’re encouraged to use the more flexible `CELERYBEAT_SCHEDULE` setting.

• Built-in daemonization support of the worker using `celery multi` is no longer experimental and is considered production quality.

  See *Generic init-scripts* if you want to use the new generic init scripts.

• Added support for message compression using the `CELERY_MESSAGE_COMPRESSION` setting, or the `compression` argument to `apply_async`. This can also be set using routers.

• **worker:** Now logs stack-trace of all threads when receiving the `SIGUSR1` signal (doesn’t work on CPython 2.4, Windows or Jython).

  Inspired by https://gist.github.com/737056

• Can now remotely terminate/kill the worker process currently processing a task.

  The `revoke` remote control command now supports a `terminate` argument Default signal is `TERM`, but can be specified using the `signal` argument. Signal can be the uppercase name of any signal defined in the `signal` module in the Python Standard Library.

  Terminating a task also revokes it.

  Example:

  ```python
  >>> from celery.task.control import revoke
  >>> revoke(task_id, terminate=True)
  >>> revoke(task_id, terminate=True, signal='KILL')
  >>> revoke(task_id, terminate=True, signal='SIGKILL')
  ```

• `TaskSetResult.join_native`: Backend-optimized version of `join()`.

  If available, this version uses the backends ability to retrieve multiple results at once, unlike `join()` which fetches the results one by one.

  So far only supported by the AMQP result backend. Support for Memcached and Redis may be added later.

• Improved implementations of `TaskSetResult.join` and `AsyncResult.wait`.

  An `interval` keyword argument have been added to both so the polling interval can be specified (default interval is 0.5 seconds).
A `propagate` keyword argument have been added to `result.wait()`, errors will be returned instead of raised if this is set to False.

**Warning:** You should decrease the polling interval when using the database result backend, as frequent polling can result in high database load.

- The PID of the child worker process accepting a task is now sent as a field with the `task-started` event.
- The following fields have been added to all events in the worker class:
  - `sw_ident`: Name of worker software (e.g., "py-celery").
  - `sw_ver`: Software version (e.g., 2.2.0).
  - `sw_sys`: Operating System (e.g., Linux, Windows, Darwin).
- For better accuracy the start time reported by the multiprocessing worker process is used when calculating task duration.

  Previously the time reported by the accept callback was used.

- **celerybeat:** New built-in daemonization support using the `--detach` option.
- **celeryev:** New built-in daemonization support using the `--detach` option.
- **TaskSet.apply_async:** Now supports custom publishers by using the `publisher` argument.
- **Added** `CELERY_SEND_TASK_SENT_EVENT` setting.
  
  If enabled an event will be sent with every task, so monitors can track tasks before the workers receive them.

- **celerybeat:** Now reuses the broker connection when calling scheduled tasks.
- The configuration module and loader to use can now be specified on the command-line.

  For example:

  ```bash
  $ celery worker --config=celeryconfig.py --loader=myloader.Loader
  ```

- **Added** signals: `beat_init` and `beat_embedded_init`
  - `celery.signals.beat_init`
    
    Dispatched when `celerybeat` starts (either standalone or embedded). Sender is the `celery.beat.Service` instance.
  - `celery.signals.beat_embedded_init`
    
    Dispatched in addition to the `beat_init` signal when `celerybeat` is started as an embedded process. Sender is the `celery.beat.Service` instance.

- Redis result backend: Removed deprecated settings `REDIS_TIMEOUT` and `REDIS_CONNECT_RETRY`.
- CentOS init-script for `celery worker` now available in `extra/centos`.
- Now depends on `pyparsing` version 1.5.0 or higher.

  There have been reported issues using Celery with `pyparsing` 1.4.x, so please upgrade to the latest version.
- Lots of new unit tests written, now with a total coverage of 95%.
Fixes

- **celeryev** Curses Monitor: Improved resize handling and UI layout (Issue #274 + Issue #276)
- AMQP Backend: Exceptions occurring while sending task results are now propagated instead of silenced.
  
  the worker will then show the full traceback of these errors in the log.
- AMQP Backend: No longer deletes the result queue after successful poll, as this should be handled by the
  `CELERY_AMQP_TASK_RESULT_EXPIRES` setting instead.
- AMQP Backend: Now ensures queues are declared before polling results.
- Windows: worker: Show error if running with `-B` option.
  
  Running `celerybeat` embedded is known not to work on Windows, so users are encouraged to run `celerybeat` as a separate service instead.
- Windows: Utilities no longer output ANSI color codes on Windows
- `camqadm`: Now properly handles `Control-c` by simply exiting instead of showing confusing traceback.
- Windows: All tests are now passing on Windows.
- Remove bin/ directory, and *scripts* section from `setup.py`.
  
  This means we now rely completely on setuptools entry-points.

Experimental

- Jython: worker now runs on Jython using the threaded pool.
  
  All tests pass, but there may still be bugs lurking around the corners.
- PyPy: worker now runs on PyPy.
  
  It runs without any pool, so to get parallel execution you must start multiple instances (e.g., using `multi`).
  
  Sadly an initial benchmark seems to show a 30% performance decrease on `pypy-1.4.1 + JIT`
  We would like to find out why this is, so stay tuned.
- `PublisherPool`: Experimental pool of task publishers and connections to be used with the `retry` argument to `apply_async`.
  
  The example code below will re-use connections and channels, and retry sending of the task message if the connection is lost.

```python
from celery import current_app

# Global pool
pool = current_app().amqp.PublisherPool(limit=10)

def my_view(request):
    with pool.acquire() as publisher:
        add.apply_async((2, 2), publisher=publisher, retry=True)
```

3.13.16 Change history for Celery 2.1

2.1.4

release-date 2010-12-03 12:00 p.m. CEST
release-by Ask Solem

Fixes

• Execution options to apply_async now takes precedence over options returned by active routers. This was a regression introduced recently (Issue #244).
• curses monitor: Long arguments are now truncated so curses doesn’t crash with out of bounds errors (Issue #235).
• multi: Channel errors occurring while handling control commands no longer crash the worker but are instead logged with severity error.
• SQLAlchemy database backend: Fixed a race condition occurring when the client wrote the pending state. Just like the Django database backend, it does no longer save the pending state (Issue #261 + Issue #262).
• Error email body now uses repr(exception) instead of str(exception), as the latter could result in Unicode decode errors (Issue #245).
• Error email timeout value is now configurable by using the EMAIL_TIMEOUT setting.
• celeryev: Now works on Windows (but the curses monitor won’t work without having curses).
• Unit test output no longer emits non-standard characters.
• worker: The broadcast consumer is now closed if the connection is reset.
• worker: Now properly handles errors occurring while trying to acknowledge the message.
• *TaskRequest.on_failure* now encodes traceback using the current file-system encoding (Issue #286).
• *EagerResult* can now be pickled (Issue #288).

### Documentation

• Adding *Contributing*.
• Added *Optimizing*.
• Added *Security* section to the FAQ.

#### 2.1.3

**release-date** 2010-11-09 05:00 p.m. CEST  
**release-by** Ask Solem

• Fixed deadlocks in *timer2* which could lead to *djcelerymon*/*celeryev* -c hanging.
• *EventReceiver*: now sends heartbeat request to find workers. This means *celeryev* and friends finds workers immediately at start-up.
• *celeryev* curses monitor: Set screen_delay to 10ms, so the screen refreshes more often.
• Fixed pickling errors when pickling *AsyncResult* on older Python versions.
• worker: prefetch count was decremented by ETA tasks even if there were no active prefetch limits.

#### 2.1.2

**release-data** TBA

### Fixes

• worker: Now sends the *task-retried* event for retried tasks.
• worker: Now honors ignore result for *WorkerLostError* and timeout errors.
• *celerybeat*: Fixed *UnboundLocalError* in *celerybeat* logging when using logging setup signals.
• worker: All log messages now includes *exc_info*.

#### 2.1.1

**release-date** 2010-10-14 02:00 p.m. CEST  
**release-by** Ask Solem
Fixes

- Now working on Windows again.
  Removed dependency on the `pwd`/`grp` modules.
- snapshots: Fixed race condition leading to loss of events.
- worker: Reject tasks with an ETA that cannot be converted to a time stamp.
  See issue #209
- concurrency.processes.pool: The semaphore was released twice for each task (both at ACK and result ready).
  This has been fixed, and it is now released only once per task.
- docs/configuration: Fixed typo `CELERYD_TASK_SOFT_TIME_LIMIT` -> `CELERYD_TASK_SOFT_TIME_LIMIT`.
  See issue #214
- control command `dump_scheduled`: was using old `.info` attribute
- multi: Fixed set changed size during iteration bug occurring in the restart command.
- worker: Accidentally tried to use additional command-line arguments.
  This would lead to an error like:
  
  ```
  got multiple values for keyword argument 'concurrency'.
  ```
  
  Additional command-line arguments are now ignored, and doesn’t produce this error. However – we do reserve the right to use positional arguments in the future, so please don’t depend on this behavior.
- celerybeat: Now respects routers and task execution options again.
- celerybeat: Now reuses the publisher instead of the connection.
- Cache result backend: Using `float` as the expires argument to `cache.set` is deprecated by the Memcached libraries, so we now automatically cast to `int`.
- unit tests: No longer emits logging and warnings in test output.

News

- Now depends on carrot version 0.10.7.
- Added `CELERY_REDIRECT_STDOUTS` and `CELERYD_REDIRECT_STDOUTS_LEVEL` settings.
  `CELERY_REDIRECT_STDOUTS` is used by the worker and beat. All output to `stdout` and `stderr` will be redirected to the current logger if enabled.
  `CELERY_REDIRECT_STDOUTS_LEVEL` decides the log level used and is `WARNING` by default.
- Added `CELERYBEAT_SCHEDULER` setting.
  This setting is used to define the default for the `-S` option to `celerybeat`.
  Example:

  ```
  CELERYBEAT_SCHEDULER = 'djcelery.schedulers.DatabaseScheduler'
  ```
- Added Task.expires: Used to set default expiry time for tasks.
• New remote control commands: `add_consumer` and `cancel_consumer`.

```python
add_consumer(queue, exchange, exchange_type, routing_key, **options)
```
Tells the worker to declare and consume from the specified declaration.

```python
cancel_consumer(queue_name)
```
Tells the worker to stop consuming from queue (by queue name).

Commands also added to `celeryctl` and `inspect`.

Example using `celeryctl` to start consuming from queue “queue”, in exchange “exchange”, of type “direct” using binding key “key”:

```
$ celeryctl inspect add_consumer queue exchange direct key
$ celeryctl inspect cancel_consumer queue
```

See [Management Command-line Utilities (inspect/control)](#) for more information about the `celeryctl` program.

Another example using `inspect`:

```python
>>> from celery.task.control import inspect
>>> inspect.add_consumer(queue='queue', exchange='exchange', ...
  exchange_type='direct', ...
  routing_key='key', ...
  durable=False, ...
  auto_delete=True)
>>> inspect.cancel_consumer('queue')
```

• `celerybeat`: Now logs the traceback if a message can’t be sent.
• `celerybeat`: Now enables a default socket timeout of 30 seconds.
• README/introduction/homepage: Added link to Flask-Celery.

### 2.1.0

**release-date** 2010-10-08 12:00 p.m. CEST

**release-by** Ask Solem

#### Important Notes

• Celery is now following the versioning semantics defined by `semver`.
  This means we’re no longer allowed to use odd/even versioning semantics By our previous version-
  ing scheme this stable release should’ve been version 2.2.
• Now depends on Carrot 0.10.7.
• No longer depends on SQLAlchemy, this needs to be installed separately if the database result backend is used.
• `django-celery` now comes with a monitor for the Django Admin interface. This can also be used if you’re not a
  Django user. (Update: Django-Admin monitor has been replaced with Flower, see the Monitoring guide).
• If you get an error after upgrading saying: `AttributeError: 'module' object has no attribute 'system',`
Then this is because the `celery.platform` module has been renamed to `celery.platforms` to not collide with the built-in `platform` module.

You have to remove the old `platform.py` (and maybe `platform.pyc`) file from your previous Celery installation.

To do this use `python` to find the location of this module:

```
$ python
>>> import celery.platform
>>> celery.platform
<module 'celery.platform' from '/opt/devel/celery/celery/platform.pyc'>
```

Here the compiled module is in `/opt/devel/celery/celery/`, to remove the offending files do:

```
$ rm -f /opt/devel/celery/celery/platform.py*
```

**News**

- **Added support for expiration of AMQP results (requires RabbitMQ 2.1.0)**

  The new configuration option `CELERY_AMQP_TASK_RESULT_EXPIRES` sets the expiry time in seconds (can be int or float):

  ```
  CELERY_AMQP_TASK_RESULT_EXPIRES = 30 * 60  # 30 minutes.
  CELERY_AMQP_TASK_RESULT_EXPIRES = 0.80     # 800 ms.
  ```

- **celeryev: Event Snapshots**

  If enabled, the worker sends messages about what the worker is doing. These messages are called “events”. The events are used by real-time monitors to show what the cluster is doing, but they’re not very useful for monitoring over a longer period of time. Snapshots let you take “pictures” of the clusters state at regular intervals. This can then be stored in a database to generate statistics with, or even monitoring over longer time periods.

  `django-celery` now comes with a Celery monitor for the Django Admin interface. To use this you need to run the `django-celery` snapshot camera, which stores snapshots to the database at configurable intervals.

  To use the Django admin monitor you need to do the following:

  1. Create the new database tables:

     ```
     $ python manage.py syncdb
     ```

  2. Start the `django-celery` snapshot camera:

     ```
     $ python manage.py celerycam
     ```

  3. Open up the django admin to monitor your cluster.

  The admin interface shows tasks, worker nodes, and even lets you perform some actions, like revoking and rate limiting tasks, and shutting down worker nodes.

  There’s also a Debian init.d script for `events` available, see *Daemonization* for more information.

  New command-line arguments to `celeryev`:

  -  `celery events --camera`: Snapshot camera class to use.
- `celery events --logfile`: Log file
- `celery events --loglevel`: Log level
- `celery events --maxrate`: Shutter rate limit.
- `celery events --freq`: Shutter frequency

The `--camera` argument is the name of a class used to take snapshots with. It must support the interface defined by `celery.events.snapshot.Polaroid`.

Shutter frequency controls how often the camera thread wakes up, while the rate limit controls how often it will actually take a snapshot. The rate limit can be an integer (snapshots/s), or a rate limit string which has the same syntax as the task rate limit strings ("200/m", "10/s", "1/h", etc).

For the Django camera case, this rate limit can be used to control how often the snapshots are written to the database, and the frequency used to control how often the thread wakes up to check if there's anything new.

The rate limit is off by default, which means it will take a snapshot for every `--frequency` seconds.

• `broadcast()`: Added callback argument, this can be used to process replies immediately as they arrive.

• `celeryctl`: New command line utility to manage and inspect worker nodes, apply tasks and inspect the results of tasks.

See also:

The *Management Command-line Utilities (inspect/control)* section in the *User Guide*.

Some examples:

```
$ celeryctl apply tasks.add -a '[2, 2]' --countdown=10
$ celeryctl inspect active
$ celeryctl inspect registered_tasks
$ celeryctl inspect scheduled
$ celeryctl inspect --help
$ celeryctl apply --help
```

• Added the ability to set an expiry date and time for tasks.

Example:

```
>>> # Task expires after one minute from now.
>>> task.apply_async(args, kwargs, expires=60)
>>> # Also supports datetime
>>> task.apply_async(args, kwargs, ... expires=datetime.now() + timedelta(days=1))
```

When a worker receives a task that’s been expired it will be marked as revoked (`TaskRevokedError`).

• Changed the way logging is configured.

We now configure the root logger instead of only configuring our custom logger. In addition we don’t hijack the multiprocessing logger anymore, but instead use a custom logger name for different applications:
This means that the `loglevel` and `logfile` arguments will affect all registered loggers (even those from third-party libraries). Unless you configure the loggers manually as shown below, that is.

Users can choose to configure logging by subscribing to the :signal:`~celery.signals.setup_logging` signal:

```python
from logging.config import fileConfig
from celery import signals

@signals.setup_logging.connect
def setup_logging(**kwargs):
    fileConfig('logging.conf')
```

If there are no receivers for this signal, the logging subsystem will be configured using the `--loglevel` `--logfile` arguments, this will be used for all defined loggers.

Remember that the worker also redirects stdout and stderr to the Celery logger, if manually configure logging you also need to redirect the standard outs manually:

```python
from logging.config import fileConfig
from celery import log

def setup_logging(**kwargs):
    import logging
    fileConfig('logging.conf')
    stdouts = logging.getLogger('mystdoutslogger')
    log.redirect_stdouts_to_logger(stdouts, loglevel=logging.WARNING)
```

- **worker** Added command line option `--include`:
  
  A comma separated list of (task) modules to be imported.

  Example:

  ```
  $ celeryd -I appl.tasks,app2.tasks
  ```

- **worker**: now emits a warning if running as the root user (euid is 0).

- `celery.messaging.establish_connection()`: Ability to override defaults used using keyword argument “defaults”.

- **worker**: Now uses `multiprocessing.freeze_support()` so that it should work with `py2exe`, `PyInstaller`, `cx_Freeze`, etc.

- **worker**: Now includes more meta-data for the `STARTED` state: PID and host name of the worker that started the task.

  See issue #181

- **subtask**: Merge additional keyword arguments to `subtask()` into task keyword arguments.

  For example:
See issue #182.

- worker: Now emits a warning if there’s already a worker node using the same name running on the same virtual host.
- AMQP result backend: Sending of results are now retried if the connection is down.
- AMQP result backend: `result.get(): Wait for next state if state isn’t` in `READY_STATES`.
- TaskSetResult now supports subscription.

```python
>>> res = TaskSet(tasks).apply_async()

res[0].get()
```

- Added `Task.send_error_emails` and `Task.error_whitelist`, so these can be configured per task instead of just by the global setting.
- Added `Task.store_errors_even_if_ignored`, so it can be changed per Task, not just by the global setting.
- The Crontab scheduler no longer wakes up every second, but implements `remaining_estimate` (Optimization).
- worker: Store `FAILURE` result if the `WorkerLostError` exception occurs (worker process disappeared).
- worker: Store `FAILURE` result if one of the `*TimeLimitExceeded` exceptions occurs.
- Refactored the periodic task responsible for cleaning up results.
  - The backend cleanup task is now only added to the schedule if
    `CELERY_TASK_RESULT_EXPIRES` is set.
  - If the schedule already contains a periodic task named “celery.backend_cleanup” it won’t change it, so the behavior of the backend cleanup task can be easily changed.
  - The task is now run every day at 4:00 AM, rather than every day since the first time it was run (using Crontab schedule instead of `run_every`)
  - Renamed `celery.task.builtins.DeleteExpiredTaskMetaTask` to `celery.task.builtins.backend_cleanup`
  - The task itself has been renamed from “celery.delete_expired_task_meta” to “celery.backend_cleanup”

See issue #134.

- Implemented `AsyncResult.forget` for SQLAlchemy/Memcached/Redis/Tokyo Tyrant backends (forget and remove task result).

```python
>>> res = TaskSet(tasks).apply_async()

res[0].get()
```

- Implemented `Task.update_state(task_id, state, meta)` as a shortcut to `task.backend.store_result(task_id, meta, state)`.
  - The backend interface is “private” and the terminology outdated, so better to move this to `Task` so it can be used.
- timer2: Set `self.running=False` in `stop()` so it won’t try to join again on subsequent calls to `stop()`.

3.13. History
• Log colors are now disabled by default on Windows.
• `celery.platform` renamed to `celery.platforms`, so it doesn’t collide with the built-in `platform` module.
• Exceptions occurring in Mediator+Pool callbacks are now caught and logged instead of taking down the worker.
• Redis result backend: Now supports result expiration using the Redis `EXPIRE` command.
• unit tests: Don’t leave threads running at tear down.
• worker: Task results shown in logs are now truncated to 46 chars.
• `Task.__name__` is now an alias to `self.__class__.__name__`. This way tasks introspects more like regular functions.
• `Task.retry`: Now raises `TypeError` if kwargs argument is empty.
  See issue #164.
• `timedelta_seconds`: Use `timedelta.total_seconds` if running on Python 2.7
• `TokenBucket`: Generic Token Bucket algorithm
• `celery.events.state`: Recording of cluster state can now be paused and resumed, including support for buffering.
  ```python
  State.freeze(buffer=True)
  # Pauses recording of the stream.
  # If buffer is true, events received while being frozen will be buffered, and may be replayed later.
  State.thaw(replay=True)
  # Resumes recording of the stream.
  # If replay is true, then the recorded buffer will be applied.
  State.freeze_while(fun)
  # With a function to apply, freezes the stream before, and replays the buffer after the function returns.
  ```
• `EventReceiver.capture` Now supports a timeout keyword argument.
• worker: The mediator thread is now disabled if `CELERY_RATE_LIMITS` is enabled, and tasks are directly sent to the pool without going through the ready queue (Optimization).

Fixes

• Pool: Process timed out by `TimeoutHandler` must be joined by the Supervisor, so don’t remove it from the internal process list.
  See issue #192.
• `TaskPublisher.delay_task` now supports exchange argument, so exchange can be overridden when sending tasks in bulk using the same publisher
  See issue #187.
• the worker no longer marks tasks as revoked if `CELERY_IGNORE_RESULT` is enabled.
  See issue #207.
• AMQP Result backend: Fixed bug with `result.get()` if `CELERY_TRACK_STARTED` enabled.
  `result.get()` would stop consuming after receiving the `STARTED` state.
Fixed bug where new processes created by the pool supervisor becomes stuck while reading from the task Queue.

See http://bugs.python.org/issue10037

Fixed timing issue when declaring the remote control command reply queue

This issue could result in replies being lost, but have now been fixed.

Backward compatible LoggerAdapter implementation: Now works for Python 2.4.

Also added support for several new methods: fatal, makeRecord, _log, log, isEnabledFor, addHandler, removeHandler.

Experimental

• multi: Added daemonization support.

multi can now be used to start, stop and restart worker nodes:

```
$ celeryd-multi start jerry elaine george kramer
```

This also creates PID files and log files (celeryd@jerry.pid, ..., celeryd@jerry.log). To specify a location for these files use the --pidfile and --logfile arguments with the %n format:

```
$ celeryd-multi start jerry elaine george kramer \
   --logfile=/var/log/celeryd@%n.log \
   --pidfile=/var/run/celeryd@%n.pid
```

Stopping:

```
$ celeryd-multi stop jerry elaine george kramer
```

Restarting. The nodes will be restarted one by one as the old ones are shutdown:

```
$ celeryd-multi restart jerry elaine george kramer
```

Killing the nodes (WARNING: Will discard currently executing tasks):

```
$ celeryd-multi kill jerry elaine george kramer
```

See celeryd-multi help for help.

• multi: start command renamed to show.

```
celeryd-multi start will now actually start and detach worker nodes. To just generate the commands you have to use celeryd-multi show.
```

• worker: Added --pidfile argument.

The worker will write its pid when it starts. The worker will not be started if this file exists and the pid contained is still alive.

• Added generic init.d script using celeryd-multi

https://github.com/celery/celery/tree/master/extra/generic-init.d/celeryd
Documentation

- Added User guide section: Monitoring
- Added user guide section: Periodic Tasks
  
  Moved from getting-started/periodic-tasks and updated.
- tutorials/external moved to new section: “community”.
- References has been added to all sections in the documentation.
  
  This makes it easier to link between documents.

3.13.17 Change history for Celery 2.0

- 2.0.3
  - Fixes
    - Documentation
- 2.0.2
- 2.0.1
- 2.0.0
  - Foreword
  - Upgrading for Django-users
  - Upgrading for others
    - Database result backend
    - Cache result backend
  - Backward incompatible changes
  - News

2.0.3

release-date  2010-08-27 12:00 p.m. CEST
release-by    Ask Solem

Fixes

- Worker: Properly handle connection errors happening while closing consumers.
- Worker: Events are now buffered if the connection is down, then sent when the connection is re-established.
- No longer depends on the mailer package.
  
  This package had a name space collision with django-mailer, so its functionality was replaced.
- Redis result backend: Documentation typos: Redis doesn’t have database names, but database numbers. The default database is now 0.
• **inspect**: `registered_tasks` was requesting an invalid command because of a typo.

  See issue #170.

• **CELERY_ROUTES**: Values defined in the route should now have precedence over values defined in **CELERY_QUEUES** when merging the two.

  With the following settings:

  ```
  CELERY_QUEUES = {'cpubound': {'exchange': 'cpubound',
                               'routing_key': 'cpubound'}}
  CELERY_ROUTES = {'tasks.add': {'queue': 'cpubound',
                                 'routing_key': 'tasks.add',
                                 'serializer': 'json'}}
  ```

  The final routing options for *tasks.add* will become:

  ```
  {'exchange': 'cpubound',
   'routing_key': 'tasks.add',
   'serializer': 'json'}
  ```

  This wasn’t the case before: the values in **CELERY_QUEUES** would take precedence.

• Worker crashed if the value of **CELERY_TASK_ERROR_WHITELIST** was not an iterable

• **apply()**: Make sure `kwargs['task_id']` is always set.

• **AsyncResult.traceback**: Now returns None, instead of raising `KeyError` if traceback is missing.

• **inspect**: Replies didn’t work correctly if no destination was specified.

• Can now store result/meta-data for custom states.

• Worker: A warning is now emitted if the sending of task error emails fails.

• **celeryev**: Curses monitor no longer crashes if the terminal window is resized.

  See issue #160.

• Worker: On macOS it isn’t possible to run `os.exec*` in a process that’s threaded.

  This breaks the SIGHUP restart handler, and is now disabled on macOS, emitting a warning instead.

  See issue #152.

• **celery.execute.trace**: Properly handle `raise(str)`, which is still allowed in Python 2.4.

  See issue #175.

• Using `urllib2` in a periodic task on macOS crashed because of the proxy auto detection used in macOS.

  This is now fixed by using a workaround. See issue #143.

• **Debian init-scripts**: Commands shouldn’t run in a sub shell

  See issue #163.

• **Debian init-scripts**: Use the absolute path of **celeryd** program to allow stat

  See issue #162.
Documentation

- **getting-started/broker-installation**: Fixed typo

  ```python
  set_permissions "" -> set_permissions ".*".
  ```

- Tasks User Guide: Added section on database transactions.
  
  See issue #169.

  
  See issue #169.

- Documented the default values for the `CELERYD_CONCURRENCY` and `CELERYD_PREFETCH_MULTIPLIER` settings.

- Tasks User Guide: Fixed typos in the subtask example

- `celery.signals`: Documented worker_process_init.

- Daemonization cookbook: Need to export DJANGO_SETTINGS_MODULE in `/etc/default/celeryd`.

- Added some more FAQs from stack overflow

- Daemonization cookbook: Fixed typo `CELERYD_LOGFILE/CELERYD_PIDFILE` to `CELERYD_LOG_FILE / CELERYD_PID_FILE`

  Also added troubleshooting section for the init-scripts.

---

**2.0.2**

**release-date** 2010-07-22 11:31 a.m. CEST

**release-by** Ask Solem

- Routes: When using the dict route syntax, the exchange for a task could disappear making the task unroutable.
  
  See issue #158.

- Test suite now passing on Python 2.4

- No longer have to type `PYTHONPATH=.` to use `celeryconfig` in the current directory.

  This is accomplished by the default loader ensuring that the current directory is in `sys.path` when loading the config module. `sys.path` is reset to its original state after loading.

  Adding the current working directory to `sys.path` without the user knowing may be a security issue, as this means someone can drop a Python module in the users directory that executes arbitrary commands. This was the original reason not to do this, but if done only when loading the config module, this means that the behavior will only apply to the modules imported in the config module, which I think is a good compromise (certainly better than just explicitly setting `PYTHONPATH=.` anyway)

- Experimental Cassandra backend added.

- Worker: SIGHUP handler accidentally propagated to worker pool processes.

  In combination with GitHub SHA@7a7c44e39344789f11b5346e9cc8340f5fe4846c this would make each child process start a new worker instance when the terminal window was closed :/

- Worker: Don’t install SIGHUP handler if running from a terminal.

  This fixes the problem where the worker is launched in the background when closing the terminal.
• Worker: Now joins threads at shutdown.
  See issue #152.
• Test tear down: Don’t use atexit but nose’s teardown() functionality instead.
  See issue #154.
• Debian worker init-script: Stop now works correctly.
• Task logger: warn method added (synonym for warning)
• Can now define a white list of errors to send error emails for.
  Example:
  
  ```python
  CELERY_TASK_ERROR_WHITELIST = ('myapp.MalformedInputError',)
  
  See issue #153.
  ```
• Worker: Now handles overflow exceptions in time.mktime while parsing the ETA field.
• LoggerWrapper: Try to detect loggers logging back to stderr/stdout making an infinite loop.
• Added celery.task.control.inspect: Inspects a running worker.
  Examples:
  
  ```python
  # Inspect a single worker
  >>> i = inspect('myworker.example.com')

  # Inspect several workers
  >>> i = inspect(['myworker.example.com', 'myworker2.example.com'])

  # Inspect all workers consuming on this vhost.
  >>> i = inspect()

  ### Methods

  # Get currently executing tasks
  >>> i.active()

  # Get currently reserved tasks
  >>> ireserved()

  # Get the current ETA schedule
  >>> ischeduled()

  # Worker statistics and info
  >>> istats()

  # List of currently revoked tasks
  >>> irevoked()

  # List of registered tasks
  >>> iregistered_tasks()
  ```
• Remote control commands dump_active/dump_reserved/dump_schedule now replies with detailed task requests.
  Containing the original arguments and fields of the task requested.
  In addition the remote control command set_loglevel has been added, this only changes the log level for the main process.
• Worker control command execution now catches errors and returns their string representation in the reply.

• Functional test suite added

    celery.tests.functional.case contains utilities to start and stop an embedded worker process, for use in functional testing.

2.0.1

release-date  2010-07-09 03:02 p.m. CEST

release-by  Ask Solem

• multiprocessing.pool: Now handles encoding errors, so that pickling errors doesn’t crash the worker processes.

• The remote control command replies wasn’t working with RabbitMQ 1.8.0’s stricter equivalence checks.

    If you’ve already hit this problem you may have to delete the declaration:

    $ camqadm exchange.delete celerycrq

    or:

    $ python manage.py camqadm exchange.delete celerycrq

• A bug sneaked in the ETA scheduler that made it only able to execute one task per second(!)

    The scheduler sleeps between iterations so it doesn’t consume too much CPU. It keeps a list of the scheduled items sorted by time, at each iteration it sleeps for the remaining time of the item with the nearest deadline. If there are no ETA tasks it will sleep for a minimum amount of time, one second by default.

    A bug sneaked in here, making it sleep for one second for every task that was scheduled. This has been fixed, so now it should move tasks like hot knife through butter.

    In addition a new setting has been added to control the minimum sleep interval; CELERYD_ETA_SCHEDULER_PRECISION. A good value for this would be a float between 0 and 1, depending on the needed precision. A value of 0.8 means that when the ETA of a task is met, it will take at most 0.8 seconds for the task to be moved to the ready queue.

• Pool: Supervisor didn’t release the semaphore.

    This would lead to a deadlock if all workers terminated prematurely.

• Added Python version trove classifiers: 2.4, 2.5, 2.6 and 2.7

• Tests now passing on Python 2.7.

• Task.__reduce__: Tasks created using the task decorator can now be pickled.

• setup.py: nose added to tests_require.

• Pickle should now work with SQLAlchemy 0.5.x

• New homepage design by Jan Henrik Helmers: http://celeryproject.org

• New Sphinx theme by Armin Ronacher: http://docs.celeryproject.org/

• Fixed “pending_xref” errors shown in the HTML rendering of the documentation. Apparently this was caused by new changes in Sphinx 1.0b2.

• Router classes in CELERY_ROUTES are now imported lazily.
Importing a router class in a module that also loads the Celery environment would cause a circular
dependency. This is solved by importing it when needed after the environment is set up.

- **CELERY_ROUTES** was broken if set to a single dict.
  
  This example in the docs should now work again:

  ```python
  CELERY_ROUTES = {'feed.tasks.import_feed': 'feeds'}
  ```

- **CREATE_MISSING_QUEUES** wasn’t honored by apply_async.

- New remote control command: `stats`

  Dumps information about the worker, like pool process ids, and total number of tasks executed by
type.

  Example reply:

  ```python
  [{
    'worker.local': {
      'total': {'tasks.sleeptask': 6},
      'pool': {'timeouts': [None, None],
               'processes': [60376, 60377],
               'max-concurrency': 2,
               'max-tasks-per-child': None,
               'put-guarded-by-semaphore': True}}
  }
  ```

- New remote control command: `dump_active`

  Gives a list of tasks currently being executed by the worker. By default arguments are passed
through repr in case there are arguments that’s not JSON encodable. If you know the arguments are
JSON safe, you can pass the argument `safe=True`.

  Example reply:

  ```python
  >>> broadcast('dump_active', arguments={'safe': False}, reply=True)
  [{
    'worker.local': [
      {'args': '(1,)','time_start': 1278580542.6300001,
       'name': 'tasks.sleeptask',
       'delivery_info': {
         'consumer_tag': '30',
         'routing_key': 'celery',
         'exchange': 'celery'},
       'hostname': 'casper.local',
       'acknowledged': True,
       'kwargs': '{}',
       'id': '802e93e9-e470-47ed-b913-06de8510aca2',
     }
    ]
  ]
  ```

- Added experimental support for persistent revokes.

  Use the `-S|--statedb` argument to the worker to enable it:

  ```bash
  $ celeryd --statedb=/var/run/celeryd
  ```

  This will use the file: `/var/run/celeryd.db`, as the `shelve` module automatically adds the `.db` suffix.
Foreword

Celery 2.0 contains backward incompatible changes, the most important being that the Django dependency has been removed so Celery no longer supports Django out of the box, but instead as an add-on package called django-celery. We’re very sorry for breaking backwards compatibility, but there’s also many new and exciting features to make up for the time you lose upgrading, so be sure to read the News section. Quite a lot of potential users have been upset about the Django dependency, so maybe this is a chance to get wider adoption by the Python community as well.

Big thanks to all contributors, testers and users!

Upgrading for Django-users

Django integration has been moved to a separate package: django-celery.

- To upgrade you need to install the django-celery module and change:

```
INSTALLED_APPS = 'celery'
```

  to:

```
INSTALLED_APPS = 'djcelery'
```

- If you use mod_wsgi you need to add the following line to your .wsgi file:

```
import os
os.environ['CELERY_LOADER'] = 'django'
```

- The following modules has been moved to django-celery:

<table>
<thead>
<tr>
<th>Module name</th>
<th>Replace with</th>
</tr>
</thead>
<tbody>
<tr>
<td>celery.models</td>
<td>djcelery.models</td>
</tr>
<tr>
<td>celery.managers</td>
<td>djcelery.managers</td>
</tr>
<tr>
<td>celery.views</td>
<td>djcelery.views</td>
</tr>
<tr>
<td>celery.urls</td>
<td>djcelery.urls</td>
</tr>
<tr>
<td>celery.management</td>
<td>djcelery.management</td>
</tr>
<tr>
<td>celery.loaders.djangoapp</td>
<td>djcelery.loaders</td>
</tr>
<tr>
<td>celery.backends.database</td>
<td>djcelery.backends.database</td>
</tr>
<tr>
<td>celery.backends.cache</td>
<td>djcelery.backends.cache</td>
</tr>
</tbody>
</table>

Importing djcelery will automatically setup Celery to use Django loader. It does this by setting the CELERY_LOADER environment variable to “django” (it won’t change it if a loader is already set). When the Django loader is used, the “database” and “cache” result backend aliases will point to the djcelery backends instead of the built-in backends, and configuration will be read from the Django settings.
Upgrading for others

Database result backend

The database result backend is now using SQLAlchemy instead of the Django ORM, see Supported Databases for a table of supported databases.

The `DATABASE_*` settings has been replaced by a single setting: `CELERY_RESULT_DBURI`. The value here should be an SQLAlchemy Connection String, some examples include:

```python
# sqlite (filename)
CELERY_RESULT_DBURI = 'sqlite:///celerydb.sqlite'

# mysql
CELERY_RESULT_DBURI = 'mysql://scott:tiger@localhost/foo'

# postgresql
CELERY_RESULT_DBURI = 'postgresql://scott:tiger@localhost/mydatabase'

# oracle
CELERY_RESULT_DBURI = 'oracle://scott:tiger@127.0.0.1:1521/sidname'
```

See SQLAlchemy Connection Strings for more information about connection strings.

To specify additional SQLAlchemy database engine options you can use the `CELERY_RESULT_ENGINE_OPTIONS` setting:

```python
# echo enables verbose logging from SQLAlchemy.
CELERY_RESULT_ENGINE_OPTIONS = {'echo': True}
```

Cache result backend

The cache result backend is no longer using the Django cache framework, but it supports mostly the same configuration syntax:

```python
CELERY_CACHE_BACKEND = 'memcached://A.example.com:11211;B.example.com'
```

To use the cache backend you must either have the pylibmc or python-memcached library installed, of which the former is regarded as the best choice.

The support backend types are `memcached://` and `memory://`, we haven’t felt the need to support any of the other backends provided by Django.

Backward incompatible changes

- Default (python) loader now prints warning on missing `celeryconfig.py` instead of raising `ImportError`.

  The worker raises `ImproperlyConfigured` if the configuration isn’t set up. This makes it possible to use `--help` etc., without having a working configuration.

  Also this makes it possible to use the client side of Celery without being configured:

```python
>>> from carrot.connection import BrokerConnection
>>> conn = BrokerConnection(('localhost', 'guest', 'guest', '/'))
>>> from celery.execute import send_task
```

(continues on next page)
>>> r = send_task('celery.ping', args=(), kwargs={}, connection=conn)
>>> from celery.backends.amqp import AMQPBackend
>>> r.backend = AMQPBackend(connection=conn)
>>> r.get()
'pong'

- The following deprecated settings has been removed (as scheduled by the *Celery Deprecation Time-line*):

<table>
<thead>
<tr>
<th>Setting name</th>
<th>Replace with</th>
</tr>
</thead>
<tbody>
<tr>
<td>CELERY_AMQP_CONSUMER_QUEUES</td>
<td>CELERY_QUEUES</td>
</tr>
<tr>
<td>CELERY_AMQP_EXCHANGE</td>
<td>CELERY_DEFAULT_EXCHANGE</td>
</tr>
<tr>
<td>CELERY_AMQP_EXCHANGE_TYPE</td>
<td>CELERY_DEFAULT_EXCHANGE_TYPE</td>
</tr>
<tr>
<td>CELERY_AMQP_CONSUMER_ROUTING_KEY</td>
<td>CELERY_QUEUES</td>
</tr>
<tr>
<td>CELERY_AMQP_PUBLISHER_ROUTING_KEY</td>
<td>CELERY_DEFAULT_ROUTING_KEY</td>
</tr>
</tbody>
</table>

- The *celery.task.rest* module has been removed, use *celery.task.http* instead (as scheduled by the *Celery Deprecation Time-line*).

- It’s no longer allowed to skip the class name in loader names. (as scheduled by the *Celery Deprecation Time-line*):

  Assuming the implicit *Loader* class name is no longer supported, for example, if you use:

  ```
  CELERY_LOADER = 'myapp.loaders'
  ```

  You need to include the loader class name, like this:

  ```
  CELERY_LOADER = 'myapp.loaders.Loader'
  ```

- **CELERY_TASK_RESULT_EXPIRES** now defaults to 1 day.
  Previous default setting was to expire in 5 days.

- AMQP backend: Don’t use different values for *auto_delete*.

  This bug became visible with RabbitMQ 1.8.0, which no longer allows conflicting declarations for the auto_delete and durable settings.

  If you’ve already used Celery with this backend chances are you have to delete the previous declaration:

  ```
  $ camqadm exchange.delete celeryresults
  ```

- Now uses pickle instead of ePickle on Python versions <= 2.5

  cPickle is broken in Python <= 2.5.

  It unsafely and incorrectly uses relative instead of absolute imports, so for example:

  ```
  exceptions.KeyError
  ```

  becomes:

  ```
  celery.exceptions.KeyError
  ```

  Your best choice is to upgrade to Python 2.6, as while the pure pickle version has worse performance, it is the only safe option for older Python versions.
News

- **celeryev**: Curses Celery Monitor and Event Viewer.

  This is a simple monitor allowing you to see what tasks are executing in real-time and investigate tracebacks and results of ready tasks. It also enables you to set new rate limits and revoke tasks.

  **Screenshot:**

  If you run `celeryev` with the `-d` switch it will act as an event dumper, simply dumping the events it receives to standard out:

  ```
  $ celeryev -d
  -> celeryev: starting capture...
  casper.local [2010-06-04 10:42:07.020000] heartbeat
  casper.local [2010-06-04 10:42:14.750000] task received:
  tasks.add(61a68756-27f4-4879-b816-3cf815672b0e) args=[2, 2] kwargs={}
  eta=2010-06-04T10:42:16.669290, retries=0
  casper.local [2010-06-04 10:42:17.230000] task started
  tasks.add(61a68756-27f4-4879-b816-3cf815672b0e) args=[2, 2] kwargs={}
  casper.local [2010-06-04 10:42:17.960000] task succeeded:
  tasks.add(61a68756-27f4-4879-b816-3cf815672b0e) args=[2, 2] kwargs={} result=4, runtime=0.782663106918
  ``

  The fields here are, in order: *sender hostname*, *timestamp*, *event type* and (continues on next page)
• AMQP result backend: Now supports .ready(), .successful(), .result, .status, and even responds to changes in task state

• New user guides:
  – Workers Guide
  – Canvas: Designing Work-flows
  – Routing Tasks

• Worker: Standard out/error is now being redirected to the log file.

• billiard has been moved back to the Celery repository.

<table>
<thead>
<tr>
<th>Module name</th>
<th>celery equivalent</th>
</tr>
</thead>
<tbody>
<tr>
<td>billiard.pool</td>
<td>celery.concurrency.processes.pool</td>
</tr>
<tr>
<td>billiard.serialization</td>
<td>celery.serialization</td>
</tr>
<tr>
<td>billiard.utils.functional</td>
<td>celery.utils.functional</td>
</tr>
</tbody>
</table>

The billiard distribution may be maintained, depending on interest.

• now depends on carrot >= 0.10.5

• now depends on pyparsing

• Worker: Added --purge as an alias to --discard.

• Worker: Control-c (SIGINT) once does warm shutdown, hitting Control-c twice forces termination.

• Added support for using complex Crontab-expressions in periodic tasks. For example, you can now use:

    >>> crontab(minute='*/15')

    or even:

    >>> crontab(minute='*/30', hour='8-17,1-2', day_of_week='thu-fri')

    See Periodic Tasks.

• Worker: Now waits for available pool processes before applying new tasks to the pool.

    This means it doesn’t have to wait for dozens of tasks to finish at shutdown because it has applied prefetched tasks without having any pool processes available to immediately accept them.

    See issue #122.

• New built-in way to do task callbacks using subtask.

    See Canvas: Designing Work-flows for more information.

• TaskSets can now contain several types of tasks.

    TaskSet has been refactored to use a new syntax, please see Canvas: Designing Work-flows for more information.

    The previous syntax is still supported, but will be deprecated in version 1.4.

• TaskSet failed() result was incorrect.

    See issue #132.
• Now creates different loggers per task class.

  See issue #129.

• Missing queue definitions are now created automatically.

  You can disable this using the CELERY_CREATE_MISSING_QUEUES setting.

  The missing queues are created with the following options:

  ```python
  CELERY_QUEUES[name] = {'exchange': name,
                         'exchange_type': 'direct',
                         'routing_key': name}
  ```

  This feature is added for easily setting up routing using the `-Q` option to the worker:

  ```bash
  $ celeryd -Q video, image
  ```

  See the new routing section of the User Guide for more information: Routing Tasks.

• New Task option: `Task.queue`

  If set, message options will be taken from the corresponding entry in CELERY_QUEUES. `exchange`, `exchange_type` and `routing_key` will be ignored

• Added support for task soft and hard time limits.

  New settings added:

  ```
  - CELERYD_TASK_TIME_LIMIT
    Hard time limit. The worker processing the task will be killed and replaced with a new one when this is exceeded.

  - CELERYD_TASK_SOFT_TIME_LIMIT
    Soft time limit. The SoftTimeLimitExceeded exception will be raised when this is exceeded. The task can catch this to, for example, clean up before the hard time limit comes.
  ```

  New command-line arguments to celeryd added: `--time-limit` and `--soft-time-limit`.

  What’s left?

  This won’t work on platforms not supporting signals (and specifically the SIGUSR1 signal) yet. So an alternative the ability to disable the feature all together on nonconforming platforms must be implemented.

  Also when the hard time limit is exceeded, the task result should be a TimeLimitExceeded exception.

• Test suite is now passing without a running broker, using the carrot in-memory backend.

• Log output is now available in colors.

<table>
<thead>
<tr>
<th>Log level</th>
<th>Color</th>
</tr>
</thead>
<tbody>
<tr>
<td>DEBUG</td>
<td>Blue</td>
</tr>
<tr>
<td>WARNING</td>
<td>Yellow</td>
</tr>
<tr>
<td>CRITICAL</td>
<td>Magenta</td>
</tr>
<tr>
<td>ERROR</td>
<td>Red</td>
</tr>
</tbody>
</table>

  This is only enabled when the log output is a tty. You can explicitly enable/disable this feature using the CELERYD_LOG_COLOR setting.

• Added support for task router classes (like the django multi-db routers)
– New setting: CELERY_ROUTES

This is a single, or a list of routers to traverse when sending tasks. Dictionaries in this list converts to a celery.routes.MapRoute instance.

Examples:

```python
>>> CELERY_ROUTES = {
    'celery.ping': 'default',
    'mytasks.add': 'cpu-bound',
    'video.encode': {
        'queue': 'video',
        'exchange': 'media',
        'routing_key': 'media.video.encode'}
}
```

```python
>>> CELERY_ROUTES = ('myapp.tasks.Router',
                   {'celery.ping': 'default'})
```

Where myapp.tasks.Router could be:

```python
class Router(object):
    def route_for_task(self, task, args=None, kwargs=None):
        if task == 'celery.ping':
            return 'default'
```

route_for_task may return a string or a dict. A string then means it’s a queue name in CELERY_QUEUES, a dict means it’s a custom route.

When sending tasks, the routers are consulted in order. The first router that doesn’t return None is the route to use. The message options is then merged with the found route settings, where the routers settings have priority.

Example if apply_async() has these arguments:

```python
>>> Task.apply_async(immediate=False, exchange='video',...
                   routing_key='video.compress')
```

and a router returns:

```python
{'immediate': True, 'exchange': 'urgent'}
```

the final message options will be:

```python
>>> task.apply_async(
...     immediate=True,
...     exchange='urgent',
...     routing_key='video.compress',
... )
```

(and any default message options defined in the Task class)

- New Task handler called after the task returns: after_return().
- ExceptionInfo now passed to on_retry()/on_failure() as einfo keyword argument.
- Worker: Added CELERYD_MAX_TASKS_PER_CHILD/ celery worker --maxtasksperchild.

  Defines the maximum number of tasks a pool worker can process before the process is terminated and replaced by a new one.
• Revoked tasks now marked with state \texttt{REVOKED}, and \texttt{result.get()} will now raise \texttt{TaskRevokedError}.

• \texttt{celery.task.control.ping()} now works as expected.

• \texttt{apply(throw=True)} / \texttt{CELERY_EAGER_PROPAGATES_EXCEPTIONS}: Makes eager execution re-raise task errors.

• New signal: \texttt{~celery.signals.worker_process_init}: Sent inside the pool worker process at init.

• Worker: \texttt{celery worker -Q} option: Ability to specify list of queues to use, disabling other configured queues.

  For example, if \texttt{CELERY_QUEUES} defines four queues: \texttt{image}, \texttt{video}, \texttt{data} and \texttt{default}, the following command would make the worker only consume from the \texttt{image} and \texttt{video} queues:

  \begin{verbatim}
  $ celeryd -Q image,video
  \end{verbatim}

• Worker: New return value for the \texttt{revoke} control command:

  Now returns:

  \begin{verbatim}
  { 'ok': 'task $id revoked'
  \end{verbatim}

  instead of \texttt{True}.

• Worker: Can now enable/disable events using remote control

  Example usage:

  \begin{verbatim}
  >>> from celery.task.control import broadcast
  >>> broadcast('enable_events')
  >>> broadcast('disable_events')
  \end{verbatim}

• Removed top-level tests directory. Test config now in \texttt{celery.tests.config}

  This means running the unit tests doesn’t require any special setup. \texttt{celery/tests/__init__} now configures the \texttt{CELERY_CONFIG_MODULE} and \texttt{CELERY_LOADER} environment variables, so when \texttt{nosedests} imports that, the unit test environment is all set up.

  Before you run the tests you need to install the test requirements:

  \begin{verbatim}
  $ pip install -r requirements/test.txt
  \end{verbatim}

  Running all tests:

  \begin{verbatim}
  $ nosetests
  \end{verbatim}

  Specifying the tests to run:

  \begin{verbatim}
  $ nosetests celery.tests.test_task
  \end{verbatim}

  Producing HTML coverage:

  \begin{verbatim}
  $ nosetests --with-coverage3
  \end{verbatim}

  The coverage output is then located in \texttt{celery/tests/cover/index.html}.

• Worker: New option \texttt{--version}: Dump version info and exit.

• \texttt{celeryd-multi}: Tool for shell scripts to start multiple workers.

  Some examples:
Advanced example with 10 workers:

* Three of the workers processes the images and video queue
* Two of the workers processes the data queue with loglevel DEBUG
* the rest processes the default' queue.

```
```

Get commands to start 10 workers, with 3 processes each

```
celeryd-multi start 3 -c 3
celeryd -n celeryd1.myhost -c 3
 celeryd -n celeryd2.myhost -c 3
 celeryd -n celeryd3.myhost -c 3
```

Start 3 named workers

```
celeryd-multi start image video data -c 3
 celeryd -n image.myhost -c 3
 celeryd -n video.myhost -c 3
 celeryd -n data.myhost -c 3
```

Specify custom hostname

```
celeryd-multi start 2 -n worker.example.com -c 3
 celeryd -n celeryd1.worker.example.com -c 3
 celeryd -n celeryd2.worker.example.com -c 3
```

Additional options are added to each celeryd, but you can also modify the options for ranges of or single workers

3 workers: Two with 3 processes, and one with 10 processes.

```
celeryd-multi start 3 -c 3 -c:1 10
 celeryd -n celeryd1.myhost -c 10
 celeryd -n celeryd2.myhost -c 3
 celeryd -n celeryd3.myhost -c 3
```

Can also specify options for named workers

```
celeryd-multi start image video data -c 3 -c:image 10
 celeryd -n image.myhost -c 10
 celeryd -n video.myhost -c 3
 celeryd -n data.myhost -c 3
```

Ranges and lists of workers in options is also allowed: (-c:1-3 can also be written as -c:1,2,3)

```
celeryd-multi start 5 -c 3 -c:1-3 10
 celeryd-multi -n celeryd1.myhost -c 10
 celeryd-multi -n celeryd2.myhost -c 10
 celeryd-multi -n celeryd3.myhost -c 10
 celeryd-multi -n celeryd4.myhost -c 3
 celeryd-multi -n celeryd5.myhost -c 3
```

Lists also work with named workers:
• The worker now calls the result backends \texttt{process\_cleanup} method \textit{after} task execution instead of before.
• AMQP result backend now supports Pika.

1.0.6

release-date 2010-06-30 09:57 a.m. CEST
release-by Ask Solem

• RabbitMQ 1.8.0 has extended their exchange equivalence tests to include auto_delete and durable. This broke the AMQP backend.

If you’ve already used the AMQP backend this means you have to delete the previous definitions:
$ camqadm exchange.delete celeryresults

or:

$ python manage.py camqadm exchange.delete celeryresults

1.0.5

**release-date** 2010-06-01 02:36 p.m. CEST

**release-by** Ask Solem

**Critical**

- INT/Control-c killed the pool, abruptly terminating the currently executing tasks.
  
  Fixed by making the pool worker processes ignore SIGINT.

- Shouldn’t close the consumers before the pool is terminated, just cancel the consumers.
  
  See issue #122.

- Now depends on **billiard** >= 0.3.1

- worker: Previously exceptions raised by worker components could stall start-up, now it correctly logs the exceptions and shuts down.

- worker: Prefetch counts was set too late. QoS is now set as early as possible, so the worker: can’t slurp in all the messages at start-up.

**Changes**

- **celery.contrib.abortable**: Aborable tasks.
  
  Tasks that defines steps of execution, the task can then be aborted after each step has completed.

- **EventDispatcher**: No longer creates AMQP channel if events are disabled

- Added required RPM package names under *bdist_rpm* section, to support building RPMs from the sources using *setup.py*.

- Running unit tests: NOSE_VERBOSE environment var now enables verbose output from Nose.

- **celery.execute.apply()**: Pass log file/log level arguments as task kwargs.
  
  See issue #110.

- **celery.execute.apply**: Should return exception, not ExceptionInfo on error.
  
  See issue #111.

- Added new entries to the **FAQs**:
  
  - Should I use retry or acks_late?
  - Can I call a task by name?
1.0.4

**release-date**  2010-05-31 09:54 a.m. CEST
**release-by**  Ask Solem

- Changelog merged with 1.0.5 as the release was never announced.

1.0.3

**release-date**  2010-05-15 03:00 p.m. CEST
**release-by**  Ask Solem

**Important notes**

- Messages are now acknowledged *just before* the task function is executed.
  
  This is the behavior we’ve wanted all along, but couldn’t have because of limitations in the multi-processing module. The previous behavior wasn’t good, and the situation worsened with the release of 1.0.1, so this change will definitely improve reliability, performance and operations in general.

  For more information please see http://bit.ly/9hom6T

  - Database result backend: result now explicitly sets `null=True` as `django-picklefield` version 0.1.5 changed the default behavior right under our noses :

    See: http://bit.ly/d5OwMr

    This means those who created their Celery tables (via `syncdb` or `celeryinit`) with `django-picklefield` versions >= 0.1.5 has to alter their tables to allow the result field to be `NULL` manually.

    MySQL:

    ```sql
    ALTER TABLE celery_taskmeta MODIFY result TEXT NULL
    ```

    PostgreSQL:

    ```sql
    ALTER TABLE celery_taskmeta ALTER COLUMN result DROP NOT NULL
    ```

- Removed `Task.rate_limit_queue_type`, as it wasn’t really useful and made it harder to refactor some parts.
- Now depends on carrot >= 0.10.4
- Now depends on billiard >= 0.3.0

**News**

- AMQP backend: Added timeout support for `result.get() / result.wait()`.
- New task option: `Task.acks_late` (default: `CELERY_ACKS_LATE`)

  Late ack means the task messages will be acknowledged **after** the task has been executed, not **just before**, which is the default behavior.

  **Note:** This means the tasks may be executed twice if the worker crashes in mid-execution. Not acceptable for most applications, but desirable for others.
• Added Crontab-like scheduling to periodic tasks.

Like a cronjob, you can specify units of time of when you’d like the task to execute. While not a full implementation of cron’s features, it should provide a fair degree of common scheduling needs.

You can specify a minute (0-59), an hour (0-23), and/or a day of the week (0-6 where 0 is Sunday, or by names: sun, mon, tue, wed, thu, fri, sat).

Examples:

```python
from celery.schedules import crontab
from celery.decorators import periodic_task

@periodic_task(run_every=crontab(hour=7, minute=30))
def every_morning():
    print('Runs every morning at 7:30a.m')

@periodic_task(run_every=crontab(hour=7, minute=30, day_of_week='mon'))
def every_monday_morning():
    print('Run every monday morning at 7:30a.m')

@periodic_task(run_every=crontab(minutes=30))
def every_hour():
    print('Runs every hour on the clock (e.g., 1:30, 2:30, 3:30 etc.).')
```

**Note:** This a late addition. While we have unit tests, due to the nature of this feature we haven’t been able to completely test this in practice, so consider this experimental.

• TaskPool.apply_async: Now supports the accept_callback argument.

• apply_async: Now raises ValueError if task args isn’t a list, or kwargs isn’t a tuple (Issue #95).

• Task.max_retries can now be None, which means it will retry forever.

• celerybeat: Now reuses the same connection when publishing large sets of tasks.

• Modified the task locking example in the documentation to use cache.add for atomic locking.

• Added experimental support for a started status on tasks.

  If Task.track_started is enabled the task will report its status as “started” when the task is executed by a worker.

  The default value is False as the normal behavior is to not report that level of granularity. Tasks are either pending, finished, or waiting to be retried. Having a “started” status can be useful for when there are long running tasks and there’s a need to report which task is currently running.

  The global default can be overridden by the CELERY_TRACK_STARTED setting.

• User Guide: New section Tips and Best Practices.

  Contributions welcome!

Remote control commands

• Remote control commands can now send replies back to the caller.

  Existing commands has been improved to send replies, and the client interface in celery.task.control has new keyword arguments: reply, timeout and limit. Where reply means it will wait for replies,
timeout is the time in seconds to stop waiting for replies, and limit is the maximum number of replies to get.

By default, it will wait for as many replies as possible for one second.

- `rate_limit(task_name, destination=all, reply=False, timeout=1, limit=0)`
  Worker returns `{'ok': message}` on success, or `{'failure': message}` on failure.

```python
>>> from celery.task.control import rate_limit
>>> rate_limit('tasks.add', '10/s', reply=True)
[{'worker1': {'ok': 'new rate limit set successfully'}},
 {'worker2': {'ok': 'new rate limit set successfully'}}]
```

- `ping(destination=all, reply=False, timeout=1, limit=0)`
  Worker returns the simple message “pong”.

```python
>>> from celery.task.control import ping
>>> ping(reply=True)
[{'worker1': 'pong'},
 {'worker2': 'pong'}]
```

- `revoke(destination=all, reply=False, timeout=1, limit=0)`
  Worker simply returns `True`.

```python
>>> from celery.task.control import revoke
>>> revoke('419e46eb-cf6a-4271-86a8-442b7124132c', reply=True)
[{'worker1': True},
 {'worker2': True}]
```

You can now add your own remote control commands!

Remote control commands are functions registered in the command registry. Registering a command is done using `celery.worker.control.Panel.register()`:

```python
from celery.task.control import Panel
@Panel.register
def reset_broker_connection(state, **kwargs):
    state.consumer.reset_connection()
    return {'ok': 'connection re-established'}
```

With this module imported in the worker, you can launch the command using `celery.task.control.broadcast`:

```python
>>> from celery.task.control import broadcast
>>> broadcast('reset_broker_connection', reply=True)
[{'worker1': {'ok': 'connection re-established'}},
 {'worker2': {'ok': 'connection re-established'}}]
```

TIP You can choose the worker(s) to receive the command by using the `destination` argument:

```python
>>> broadcast('reset_broker_connection', destination=['worker1'])
[{'worker1': {'ok': 'connection re-established'}}]
```

- New remote control command: `dump_reserved`
  Dumps tasks reserved by the worker, waiting to be executed:
>>> from celery.task.control import broadcast
>>> broadcast('dump_reserved', reply=True)
[['myworker1': [TaskRequest ...]]]

- New remote control command: *dump_schedule*

Dumps the workers currently registered ETA schedule. These are tasks with an *eta* (or *countdown*) argument waiting to be executed by the worker.

>>> from celery.task.control import broadcast
>>> broadcast('dump_schedule', reply=True)
[['w1': []],
 ['w3': []],
 ['w2': ['0. 2010-05-12 11:06:00 pri0 <TaskRequest
  name:opalfeeds.tasks.refresh_feed_slice',
  id:'95b45760-4e73-4ce8-beac-f100aa80273a',
  args:('(Feeds freq_max:3600 freq_min:60
          start:2184.0 stop:3276.0)',),
  kwargs: {'page': 2}')],
 ['w4': ['0. 2010-05-12 11:00:00 pri0 <TaskRequest
  name:opalfeeds.tasks.refresh_feed_slice',
  id:'c053480b-58fb-422f-ae68-8d30a464edfe',
  args:('(Feeds freq_max:3600 freq_min:60
          start:1092.0 stop:2184.0)',),
  kwargs: {'page': 1}')],
 '1. 2010-05-12 11:12:00 pri0 <TaskRequest
  name:opalfeeds.tasks.refresh_feed_slice',
  id:'ab8bc59e-6cf8-44b8-88d0-flaf57789758',
  args:('(Feeds freq_max:3600 freq_min:60
          start:3276.0 stop:4365)',),
  kwargs: {'page': 3}]]

Fixes

- Mediator thread no longer blocks for more than 1 second.
  With rate limits enabled and when there was a lot of remaining time, the mediator thread could block shutdown (and potentially block other jobs from coming in).
- Remote rate limits wasn’t properly applied (Issue #98).
- Now handles exceptions with Unicode messages correctly in *TaskRequest.on_failure*.
- Database backend: *TaskMeta.result*: default value should be *None* not empty string.

1.0.2

**release-date** 2010-03-31 12:50 p.m. CET

**release-by** Ask Solem

- Deprecated: *CELERY_BACKEND*, please use *CELERY_RESULT_BACKEND* instead.
- We now use a custom logger in tasks. This logger supports task magic keyword arguments in formats.
  The default format for tasks (CELERYD_TASK_LOG_FORMAT) now includes the id and the name of tasks so the origin of task log messages can easily be traced.
Example output:

```
[2010-03-25 13:11:20,317: INFO/PoolWorker-1] [tasks.add(a6e1c5ad-60d9-42a0-8b24-9e39363125a4)] Hello from add
```

To revert to the previous behavior you can set:

```python
CELERYD_TASK_LOG_FORMAT = "
    [%(asctime)s: %levelname/%processName] %(message)s
".strip()
```

- Unit tests: Don’t disable the django test database tear down, instead fixed the underlying issue which was caused by modifications to the `DATABASE_NAME` setting (Issue #82).
- Django Loader: New config `CELERY_DB_REUSE_MAX` (max number of tasks to reuse the same database connection)

The default is to use a new connection for every task. We’d very much like to reuse the connection, but a safe number of reuses isn’t known, and we don’t have any way to handle the errors that might happen, which may even be database dependent.

- worker: The worker components are now configurable: `CELERYD_POOL`, `CELERYD_CONSUMER`, `CELERYD_MEDIATOR`, and `CELERYD_ETA_SCHEDULER`.

The default configuration is as follows:

```python
CELERYD_POOL = 'celery.concurrency.processes.TaskPool'
CELERYD_MEDIATOR = 'celery.worker.controllers.Mediator'
CELERYD_ETA_SCHEDULER = 'celery.worker.controllers.ScheduleController'
CELERYD_CONSUMER = 'celery.worker.consumer.Consumer'
```

The `CELERYD_POOL` setting makes it easy to swap out the multiprocessing pool with a threaded pool, or how about a twisted/eventlet pool?

Consider the competition for the first pool plug-in started!

- Debian init-scripts: Use `-a` not `&&` (Issue #82).
- Debian init-scripts: Now always preserves `$CELERYD_OPTS` from the `/etc/default/celeryd` and `/etc/default/celerybeat`.
- celery.beat.Scheduler: Fixed a bug where the schedule wasn’t properly flushed to disk if the schedule hadn’t been properly initialized.
- celerybeat: Now syncs the schedule to disk when receiving the SIGTERM and SIGINT signals.
- Control commands: Make sure keywords arguments aren’t in Unicode.
- ETA scheduler: Was missing a logger object, so the scheduler crashed when trying to log that a task had been revoked.
- `management.commands.camqadm`: Fixed typo `camqpadm` -> `camqadm` (Issue #83).
- `PeriodicTask.delta_resolution`: wasn’t working for days and hours, now fixed by rounding to the nearest day/hour.
- Fixed a potential infinite loop in `BaseAsyncResult.__eq__`, although there’s no evidence that it has ever been triggered.
- worker: Now handles messages with encoding problems by acking them and emitting an error message.
1.0.1

**release-date** 2010-02-24 07:05 p.m. CET

**release-by** Ask Solem

- Tasks are now acknowledged early instead of late.

  This is done because messages can only be acknowledged within the same connection channel, so if the connection is lost we’d’ve to re-fetch the message again to acknowledge it.

  This might or might not affect you, but mostly those running tasks with a really long execution time are affected, as all tasks that’s made it all the way into the pool needs to be executed before the worker can safely terminate (this is at most the number of pool workers, multiplied by the `CELERYD_PREFETCH_MULTIPLIER` setting).

  We multiply the prefetch count by default to increase the performance at times with bursts of tasks with a short execution time. If this doesn’t apply to your use case, you should be able to set the prefetch multiplier to zero, without sacrificing performance.

  **Note:** A patch to `multiprocessing` is currently being worked on, this patch would enable us to use a better solution, and is scheduled for inclusion in the 2.0.0 release.

- The worker now shutdowns cleanly when receiving the `SIGTERM` signal.

- The worker now does a cold shutdown if the `SIGINT` signal is received (`Control-c`), this means it tries to terminate as soon as possible.

- Caching of results now moved to the base backend classes, so no need to implement this functionality in the base classes.

- Caches are now also limited in size, so their memory usage doesn’t grow out of control.

  You can set the maximum number of results the cache can hold using the `CELERY_MAX_CACHED_RESULTS` setting (the default is five thousand results). In addition, you can re-fetch already retrieved results using `backend.reload_task_result + backend.reload_taskset_result` (that’s for those who want to send results incrementally).

- The worker now works on Windows again.

  **Warning:** If you’re using Celery with Django, you can’t use `project.settings` as the settings module name, but the following should work:

  ```shell
  $ python manage.py celeryd --settings=settings
  ```

- Execution: `.messaging.TaskPublisher.send_task` now incorporates all the functionality `apply_async` previously did.

  Like converting countdowns to ETA, so `celery.execute.apply_async()` is now simply a convenient front-end to `celery.messaging.TaskPublisher.send_task()`, using the task classes default options.

  Also `celery.execute.send_task()` has been introduced, which can apply tasks using just the task name (useful if the client doesn’t have the destination task in its task registry).

  Example:

---

3.13. History

---
>>> from celery.execute import send_task
>>> result = send_task('celery.ping', args=[], kwargs={})
>>> result.get()
'pong'

- **camqadm**: This is a new utility for command-line access to the AMQP API.

  Excellent for deleting queues/bindings/exchanges, experimentation and testing:

  ```
  $ camqadm
  1> help
  
  Gives an interactive shell, type *help* for a list of commands.
  
  When using Django, use the management command instead:

  ```
  $ python manage.py camqadm
  1> help
  ```

- Redis result backend: To conform to recent Redis API changes, the following settings has been deprecated:

  - `REDIS_TIMEOUT`
  - `REDIS_CONNECT_RETRY`

  These will emit a `DeprecationWarning` if used.

  A `REDIS_PASSWORD` setting has been added, so you can use the new simple authentication mechanism in Redis.

- The redis result backend no longer calls `SAVE` when disconnecting, as this is apparently better handled by Redis itself.

- If `settings.DEBUG` is on, the worker now warns about the possible memory leak it can result in.

- The ETA scheduler now sleeps at most two seconds between iterations.

- The ETA scheduler now deletes any revoked tasks it might encounter.

  As revokes aren’t yet persistent, this is done to make sure the task is revoked even though, for example, it’s currently being hold because its ETA is a week into the future.

- The `task_id` argument is now respected even if the task is executed eagerly (either using apply, or `CELERY_ALWAYS_EAGER`).

- The internal queues are now cleared if the connection is reset.

- New magic keyword argument: `delivery_info`.

  Used by retry() to resend the task to its original destination using the same exchange/routing_key.

- Events: Fields wasn’t passed by `.send()` (fixes the UUID key errors in celerymon)

- Added `--schedule/-s` option to the worker, so it is possible to specify a custom schedule filename when using an embedded `celerybeat` server (the `-B/–beat` option).

- Better Python 2.4 compatibility. The test suite now passes.

- task decorators: Now preserve docstring as `cls.__doc__`, (was previously copied to `cls.run.__doc__`)

- The `testproj` directory has been renamed to `tests` and we’re now using `nose + django-nose` for test discovery, and `unittest2` for test cases.

- New pip requirements files available in `requirements`.
• TaskPublisher: Declarations are now done once (per process).

• Added Task.delivery_mode and the CELERY_DEFAULT_DELIVERY_MODE setting.
  
  These can be used to mark messages non-persistent (i.e., so they’re lost if the broker is restarted).

• Now have our own ImproperlyConfigured exception, instead of using the Django one.

• Improvements to the Debian init-scripts: Shows an error if the program is not executable. Does not modify CELERYD when using django with virtualenv.

1.0.0

  release-date 2010-02-10 04:00 p.m. CET
  release-by Ask Solem

**Backward incompatible changes**

• Celery doesn’t support detaching anymore, so you have to use the tools available on your platform, or something like supervisor to make celeryd/celerybeat/celerymon into background processes.

  We’ve had too many problems with the worker daemonizing itself, so it was decided it has to be removed. Example start-up scripts has been added to the extra/ directory:

  - Debian, Ubuntu, (start-stop-daemon)
    
    extra/debian/init.d/celeryd extra/debian/init.d/celerybeat
  
  - macOS launchd
    
    extra/mac/org.celeryq.celeryd.plist extra/mac/org.celeryq.celerybeat.plist extra/mac/org.celeryq.celerymon.plist
  
  - Supervisor (http://supervisord.org)
    
    extra/supervisord/supervisord.conf

  In addition to –detach, the following program arguments has been removed: –uid, –gid, –workdir, –chroot, –pidfile, –umask. All good daemonization tools should support equivalent functionality, so don’t worry.

  Also the following configuration keys has been removed: CELERYD_PID_FILE, CELERYBEAT_PID_FILE, CELERYMON_PID_FILE.

• Default worker loglevel is now WARN, to enable the previous log level start the worker with –loglevel=INFO.

• Tasks are automatically registered.

  This means you no longer have to register your tasks manually. You don’t have to change your old code right away, as it doesn’t matter if a task is registered twice.

  If you don’t want your task to be automatically registered you can set the abstract attribute

  ```python
  class MyTask(Task):
    abstract = True
  ```

  By using abstract only tasks subclassing this task will be automatically registered (this works like the Django ORM).

  If you don’t want subclasses to be registered either, you can set the autoregister attribute to False.

3.13. History
Incidentally, this change also fixes the problems with automatic name assignment and relative imports. So you also don’t have to specify a task name anymore if you use relative imports.

- You can no longer use regular functions as tasks.
  
  This change was added because it makes the internals a lot more clean and simple. However, you can now turn functions into tasks by using the `@task` decorator:

```python
from celery.decorators import task
task()
def add(x, y):
    return x + y
```

See also:

*Tasks* for more information about the task decorators.

- The periodic task system has been rewritten to a centralized solution.
  
  This means the worker no longer schedules periodic tasks by default, but a new daemon has been introduced: *celerybeat*.

  To launch the periodic task scheduler you have to run *celerybeat*:

```bash
$ celerybeat
```

Make sure this is running on one server only, if you run it twice, all periodic tasks will also be executed twice.

If you only have one worker server you can embed it into the worker like this:

```bash
$ celeryd --beat # Embed celerybeat in celeryd.
```

- The supervisor has been removed.
  
  This means the `-S` and `–supervised` options to *celeryd* is no longer supported. Please use something like [http://supervisord.org](http://supervisord.org) instead.

- `TaskSet.join` has been removed, use `TaskSetResult.join` instead.

- The task status “DONE” has been renamed to “SUCCESS”.

- `AsyncResult.is_done` has been removed, use `AsyncResult.successful` instead.

- The worker no longer stores errors if `Task.ignore_result` is set, to revert to the previous behavior set `CELERY_STORE_ERRORS_EVEN_IF_IGNORED` to `True`.

- The statistics functionality has been removed in favor of events, so the `-S` and `–statistics` switches has been removed.

- The module *celery.task.strategy* has been removed.

- *celery.discovery* has been removed, and it’s `autodiscover` function is now in *celery.loaders.djangoapp*.

  Reason: Internal API.

- The `CELERY_LOADER` environment variable now needs loader class name in addition to module name,

  For example, where you previously had: “*celery.loaders.default*”, you now need “*celery.loaders.default.Loader*”, using the previous syntax will result in a `DeprecationWarning`.

- Detecting the loader is now lazy, and so isn’t done when importing *celery.loaders*. 

To make this happen, `celery.loaders.settings` has been renamed to `load_settings` and is now a function returning the settings object. `celery.loaders.current_loader` is now also a function, returning the current loader.

So:

```
loader = current_loader
```

needs to be changed to:

```
loader = current_loader()
```

## Deprecations

- The following configuration variables has been renamed and will be deprecated in v2.0:
  - `CELERYD_DAEMON_LOG_FORMAT` -> `CELERYD_LOG_FORMAT`
  - `CELERYD_DAEMON_LOG_LEVEL` -> `CELERYD_LOG_LEVEL`
  - `CELERY_AMQP_CONNECTION_TIMEOUT` -> `CELERY_BROKER_CONNECTION_TIMEOUT`
  - `CELERY_AMQP_CONNECTION_RETRY` -> `CELERY_BROKER_CONNECTION_RETRY`
  - `CELERY_AMQP_CONNECTION_MAX_RETRIES` -> `CELERY_BROKER_CONNECTION_MAX_RETRIES`
  - `SEND_CELERY_TASK_ERROR>Emails` -> `CELERY_SEND_TASK_ERROR_EMAILS`

- The public API names in `celery.conf` has also changed to a consistent naming scheme.

- We now support consuming from an arbitrary number of queues.

  To do this we had to rename the configuration syntax. If you use any of the custom AMQP routing options (queue/exchange/routing_key, etc.), you should read the new FAQ entry: Can I send some tasks to only some servers?.

  The previous syntax is deprecated and scheduled for removal in v2.0.

- `TaskSet.run` has been renamed to `TaskSet.apply_async`.

  `TaskSet.run` has now been deprecated, and is scheduled for removal in v2.0.

## News

- Rate limiting support (per task type, or globally).
- New periodic task system.
- Automatic registration.
- New cool task decorator syntax.
- worker: now sends events if enabled with the `-E` argument.

  Excellent for monitoring tools, one is already in the making (https://github.com/celery/celerymon).

  Current events include: `worker-heartbeat`, task-[received/succeeded/failed/retried], `worker-online`, `worker-offline`.

- You can now delete (revoke) tasks that’s already been applied.
- You can now set the hostname the worker identifies as using the `--hostname` argument.
• Cache backend now respects the `CELERY_TASK_RESULT_EXPIRES` setting.

• Message format has been standardized and now uses ISO-8601 format for dates instead of datetime.

• worker now responds to the `SIGHUP` signal by restarting itself.

• Periodic tasks are now scheduled on the clock.

  That is, `timedelta(hours=1)` means every hour at :00 minutes, not every hour from the server starts.
  To revert to the previous behavior you can set `PeriodicTask.relative = True`.

• Now supports passing execute options to a TaskSets list of args.

  Example:

  ```python
  >>> ts = TaskSet(add, 
  [(2, 2), {}, {'countdown': 1}),
  ..., 
  (4, 4), {}, {'countdown': 2}),
  ..., 
  (8, 8), {}, {'countdown': 3}])
  >>> ts.run()
  ```

• Got a 3x performance gain by setting the prefetch count to four times the concurrency, (from an average task round-trip of 0.1s to 0.03s!).

  A new setting has been added: `CELERYD_PREFETCH_MULTIPLIER`, which is set to 4 by default.

• Improved support for webhook tasks.

  `celery.task.rest` is now deprecated, replaced with the new and shiny `celery.task.http`. With more reflective names, sensible interface, and it’s possible to override the methods used to perform HTTP requests.

• The results of task sets are now cached by storing it in the result backend.

**Changes**

• Now depends on `carrot >= 0.8.1`

• New dependencies: `billiard`, `python-dateutil`, `django-picklefield`.

• No longer depends on `python-daemon`

• The `uuid` distribution is added as a dependency when running Python 2.4.

• Now remembers the previously detected loader by keeping it in the `CELERY_LOADER` environment variable.

  This may help on windows where fork emulation is used.

• ETA no longer sends datetime objects, but uses ISO 8601 date format in a string for better compatibility with other platforms.

• No longer sends error mails for retried tasks.

• Task can now override the backend used to store results.

• Refactored the ExecuteWrapper, `apply` and `CELERY_ALWAYS_EAGER` now also executes the task callbacks and signals.

• Now using a proper scheduler for the tasks with an ETA.

  This means waiting ETA tasks are sorted by time, so we don’t have to poll the whole list all the time.

• Now also imports modules listed in `CELERY_IMPORTS` when running with `django` (as documented).

• Log level for stdout/stderr changed from INFO to ERROR
• ImportErrors are now properly propagated when auto-discovering tasks.
• You can now use `celery.messaging.establish_connection` to establish a connection to the broker.
• When running as a separate service the periodic task scheduler does some smart moves to not poll too regularly.
  
  If you need faster poll times you can lower the value of `CELERYBEAT_MAX_LOOP_INTERVAL`.
• You can now change periodic task intervals at runtime, by making `run_every` a property, or subclassing `PeriodicTask.is_due`.
• The worker now supports control commands enabled through the use of a broadcast queue, you can remotely revoke tasks or set the rate limit for a task type. See `celery.task.control`.
• The services now sets informative process names (as shown in `ps` listings) if the `setproctitle` module is installed.
• `NotRegistered` now inherits from `KeyError`, and `TaskRegistry.__getitem__` + `pop` raises `NotRegistered` instead
• You can set the loader via the `CELERY_LOADER` environment variable.
• You can now set `CELERY_IGNORE_RESULT` to ignore task results by default (if enabled, tasks doesn’t save results or errors to the backend used).
• The worker now correctly handles malformed messages by throwing away and acknowledging the message, instead of crashing.

**Bugs**

• Fixed a race condition that could happen while storing task results in the database.

**Documentation**

• Reference now split into two sections: API reference and internal module reference.

**0.8.4**

`release-date` 2010-02-05 01:52 p.m. CEST

`release-by` Ask Solem

• Now emits a warning if the `--detach` argument is used. `--detach` shouldn’t be used anymore, as it has several not easily fixed bugs related to it. Instead, use something like start-stop-daemon, `supervisor` or `launchd` (macOS).
• Make sure logger class is process aware, even if running Python >= 2.6.
• Error emails are not sent anymore when the task is retried.

**0.8.3**

`release-date` 2009-12-22 09:43 a.m. CEST

`release-by` Ask Solem

• Fixed a possible race condition that could happen when storing/querying task results using the database backend.
• Now has console script entry points in the `setup.py` file, so tools like `zc.buildout` will correctly install the programs `celeryd` and `celeryinit`.

3.13. History
0.8.2

**release-date** 2009-11-20 03:40 p.m. CEST

**release-by** Ask Solem

- QOS Prefetch count wasn’t applied properly, as it was set for every message received (which apparently behaves like, “receive one more”), instead of only set when our wanted value changed.

0.8.1

**release-date** 2009-11-16 05:21 p.m. CEST

**release-by** Ask Solem

**Very important note**

This release (with carrot 0.8.0) enables AMQP QoS (quality of service), which means the workers will only receive as many messages as it can handle at a time. As with any release, you should test this version upgrade on your development servers before rolling it out to production!

**Important changes**

- If you’re using Python < 2.6 and you use the multiprocessing backport, then multiprocessing version 2.6.2.1 is required.
- All AMQP_* settings has been renamed to BROKER_*-, and in addition AMQP_SERVER has been renamed to BROKER_HOST, so before where you had:

  ```
  AMQP_SERVER = 'localhost'
  AMQP_PORT = 5678
  AMQP_USER = 'myuser'
  AMQP_PASSWORD = 'mypassword'
  AMQP_VHOST = 'celery'
  ```

  You need to change that to:

  ```
  BROKER_HOST = 'localhost'
  BROKER_PORT = 5678
  BROKER_USER = 'myuser'
  BROKER_PASSWORD = 'mypassword'
  BROKER_VHOST = 'celery'
  ```

- Custom carrot backends now need to include the backend class name, so before where you had:

  ```
  CARROT_BACKEND = 'mycustom.backend.module'
  ```

  you need to change it to:

  ```
  CARROT_BACKEND = 'mycustom.backend.module.Backend'
  ```

  where Backend is the class name. This is probably “Backend”, as that was the previously implied name.
- New version requirement for carrot: 0.8.0
Changes

- Incorporated the multiprocessing backport patch that fixes the `processName` error.
- Ignore the result of PeriodicTask’s by default.
- Added a Redis result store backend
- Allow `/etc/default/celeryd` to define additional options for the `celeryd` init-script.
- MongoDB periodic tasks issue when using different time than UTC fixed.
- Windows specific: Negate test for available `os.fork` (thanks @miracle2k).
- Now tried to handle broken PID files.
- Added a Django test runner to contrib that sets `CELERY_ALWAYS_EAGER = True` for testing with the database backend.
- Added a `CELERY_CACHE_BACKEND` setting for using something other than the Django-global cache backend.
- Use custom implementation of `functools.partial` for Python 2.4 support (Probably still problems with running on 2.4, but it will eventually be supported)
- Prepare exception to pickle when saving `RETRY` status for all backends.
- SQLite no concurrency limit should only be effective if the database backend is used.

0.8.0

**release-date** 2009-09-22 03:06 p.m. CEST

**release-by** Ask Solem

Backward incompatible changes

- Add traceback to result value on failure.

**Note:** If you use the database backend you have to re-create the database table `celery_taskmeta`.

Contact the [Mailing list](#) or IRC channel for help doing this.

- Database tables are now only created if the database backend is used, so if you change back to the database backend at some point, be sure to initialize tables (django: `syncdb`, python: `celeryinit`).

**Note:** This is only applies if using Django version 1.1 or higher.

- Now depends on `carrot` version 0.6.0.
- Now depends on python-daemon 1.4.8

Important changes

- Celery can now be used in pure Python (outside of a Django project).
This means Celery is no longer Django specific.

For more information see the FAQ entry Is Celery for Django only?

- Celery now supports task retries.
  See Retrying for more information.
- We now have an AMQP result store backend.
  It uses messages to publish task return value and status. And it’s incredibly fast!
  See issue #6 for more info!
- AMQP QoS (prefetch count) implemented:
  This to not receive more messages than we can handle.
- Now redirects stdout/stderr to the workers log file when detached
- Now uses inspect.getargspec to only pass default arguments the task supports.
- Add Task.on_success, .on_retry, .on_failure handlers
  See celery.task.base.Task.on_success(), celery.task.base.Task.on_retry(), celery.task.base.Task.on_failure(),
- celery.utils.gen_unique_id: Workaround for http://bugs.python.org/issue4607
- You can now customize what happens at worker start, at process init, etc., by creating your own loaders
  (see celery.loaders.default, celery.loaders.djangoapp, celery.loaders).
- Support for multiple AMQP exchanges and queues.
  This feature misses documentation and tests, so anyone interested is encouraged to improve this situation.
- The worker now survives a restart of the AMQP server!
  Automatically re-establish AMQP broker connection if it’s lost.

New settings:

- AMQP_CONNECTION_RETRY Set to True to enable connection retries.
- AMQP_CONNECTION_MAX_RETRIES Maximum number of restarts before we give up. Default: 100.

News

- Fix an incompatibility between python-daemon and multiprocessing, which resulted in the [Errno 10] No child processes problem when detaching.
- Fixed a possible DjangoUnicodeDecodeError being raised when saving pickled data to Django’s Memcached cache backend.
- Better Windows compatibility.
- New version of the pickled field (taken from http://www.djangosnippets.org/snippets/513/)
- New signals introduced: task_sent, task_prerun and task_postrun, see celery.signals for more information.
- TaskSetResult.join caused TypeError when timeout=None. Thanks Jerzy Kozera. Closes #31
- views.apply should return HttpResponse instance. Thanks to Jerzy Kozera. Closes #32
• **PeriodicTask**: Save conversion of `run_every` from `int` to `timedelta` to the class attribute instead of on the instance.

• Exceptions has been moved to `celery.exceptions`, but are still available in the previous module.

• Try to rollback transaction and retry saving result if an error happens while setting task status with the database backend.

• `jail()` refactored into `celery.execute.ExecuteWrapper`.

• `views.apply` now correctly sets mime-type to “application/json”

• `views.task_status` now returns exception if state is `RETRY`

• `views.task_status` now returns traceback if state is `FAILURE` or `RETRY`

• Documented default task arguments.

• Add a sensible `__repr__` to `ExceptionInfo` for easier debugging

• Fix documentation typo: `.. import map` -> `.. import dmap`. Thanks to @mikedizon.

0.6.0

release-date 2009-08-07 06:54 a.m. CET
release-by Ask Solem

**Important changes**

• Fixed a bug where tasks raising unpickleable exceptions crashed pool workers. So if you’ve had pool workers mysteriously disappearing, or problems with the worker stopping working, this has been fixed in this version.

• Fixed a race condition with periodic tasks.

• **The task pool is now supervised, so if a pool worker crashes**, goes away or stops responding, it is automatically replaced with a new one.

• Task.name is now automatically generated out of class module+name, for example “`djangotwitter.tasks.UpdateStatusesTask`”. Very convenient. No idea why we didn’t do this before. Some documentation is updated to not manually specify a task name.

**News**

• Tested with Django 1.1

• New Tutorial: Creating a click counter using Carrot and Celery

• **Database entries for periodic tasks are now created at the workers** start-up instead of for each check (which has been a forgotten TODO/XXX in the code for a long time)

• **New settings variable**: `CELERY_TASK_RESULT_EXPIRES` Time (in seconds, or a `datetime.timedelta` object) for when after stored task results are deleted. For the moment this only works for the database backend.

• The worker now emits a debug log message for which periodic tasks has been launched.

• The periodic task table is now locked for reading while getting periodic task status (MySQL only so far, seeking patches for other engines)
• A lot more debugging information is now available by turning on the `DEBUG` log level (`-loglevel=DEBUG`).
• Functions/methods with a timeout argument now works correctly.
• **New:** `celery.strategy.even_time_distribution`: With an iterator yielding task args, kwargs tuples, evenly distribute the processing of its tasks throughout the time window available.
• Log message `Unknown task ignored . . .` now has log level `ERROR`.
• Log message when task is received is now emitted for all tasks, even if the task has an ETA (estimated time of arrival). Also the log message now includes the ETA for the task (if any).
• Acknowledgment now happens in the pool callback. Can’t do ack in the job target, as it’s not pickleable (can’t share AMQP connection, etc.).
• Added note about `.delay` hanging in README
• Tests now passing in Django 1.1
• Fixed discovery to make sure app is in INSTALLED_APPS
• **Previously overridden pool behavior (process reap, wait until pool worker available, etc.)** is now handled by `multiprocessing.Pool` itself.
• Convert statistics data to Unicode for use as kwargs. Thanks Lucy!

### 0.4.1

- **release-date** 2009-07-02 01:42 p.m. CET
- **release-by** Ask Solem
- Fixed a bug with parsing the message options (`mandatory`, `routing_key`, `priority`, `immediate`)

### 0.4.0

- **release-date** 2009-07-01 07:29 p.m. CET
- **release-by** Ask Solem
- Adds eager execution. `celery.execute.apply`'s `Task.apply` executes the function blocking until the task is done, for API compatibility it returns a `celery.result.EagerResult` instance. You can configure Celery to always run tasks locally by setting the `CELERY_ALWAYS_EAGER` setting to `True`.
- Now depends on `anyjson`.
- 99% coverage using Python `coverage` 3.0.

### 0.3.20

- **release-date** 2009-06-25 08:42 p.m. CET
- **release-by** Ask Solem
- New arguments to `apply_async` (the advanced version of `delay_task`), `countdown` and `eta`;

```python
>>> # Run 10 seconds into the future.
>>> res = apply_async(MyTask, countdown=10);
```
- Now unlinks stale PID files
- Lots of more tests.
- Now compatible with carrot &ge; 0.5.0.
- **IMPORTANT** The `subtask_ids` attribute on the `TaskSetResult` instance has been removed. To get this information instead use:

```python
>>> subtask_ids = [subtask.id for subtask in ts_res.subtasks]
```

- `Taskset.run()` now respects extra message options from the task class.
- Task: Add attribute `ignore_result`: Don’t store the status and return value. This means you can’t use the `celery.result.AsyncResult` to check if the task is done, or get its return value. Only use if you need the performance and is able live without these features. Any exceptions raised will store the return value/status as usual.
- Task: Add attribute `disable_error_emails` to disable sending error emails for that task.
- Should now work on Windows (although running in the background won’t work, so using the `–detach` argument results in an exception being raised).
- Added support for statistics for profiling and monitoring. To start sending statistics start the worker with the `–statistics` option. Then after a while you can dump the results by running `python manage.py celerystats`. See `celery.monitoring` for more information.
- The Celery daemon can now be supervised (i.e., it is automatically restarted if it crashes). To use this start the worker with the `–supervised` option (or alternatively `-S`).
- `views.apply`: View calling a task.
  
  Example:

```python
http://e.com/celery/apply/task_name/arg1/arg2/?kwarg1=a&kwarg2=b
```

**Warning:** Use with caution! Don’t expose this URL to the public without first ensuring that your code is safe!

- Refactored `celery.task`. It’s now split into three modules:
  - `celery.task`
    
    Contains `apply_async`, `delay_task`, `discard_all`, and task shortcuts, plus imports objects from `celery.task.base` and `celery.task.builtins`
  - `celery.task.base`

    Contains task base classes: `Task`, `PeriodicTask`, `TaskSet`, `AsynchronousMapTask`, `ExecuteRemoteTask`.
  - `celery.task.builtins`

    Built-in tasks: `PingTask`, `DeleteExpiredTaskMetaTask`.

3.13. History 721
0.3.7

release-date  2008-06-16 11:41 p.m. CET
release-by   Ask Solem

- IMPORTANT Now uses AMQP's `basic.consume` instead of `basic.get`. This means we’re no longer polling the broker for new messages.
- IMPORTANT Default concurrency limit is now set to the number of CPUs available on the system.
- IMPORTANT `tasks.register`: Renamed `task_name` argument to `name`, so:

```python
>>> tasks.register(func, task_name='mytask')
```

has to be replaced with:

```python
>>> tasks.register(func, name='mytask')
```

- The daemon now correctly runs if the pidfile is stale.
- Now compatible with carrot 0.4.5
- Default AMQP connection timeout is now 4 seconds.
- `AsyncResult.read()` was always returning `True`.
- Only use README as long_description if the file exists so easy_install doesn’t break.
- `celery.view`: JSON responses now properly set its mime-type.
- `apply_async` now has a `connection` keyword argument so you can re-use the same AMQP connection if you want to execute more than one task.
- Handle failures in task_status view such that it won’t throw 500s.
- Fixed typo `AMQP_SERVER` in documentation to `AMQP_HOST`.
- Worker exception emails sent to administrators now works properly.
- No longer depends on `django`, so installing `celery` won’t affect the preferred Django version installed.
- Now works with PostgreSQL (`psycopg2`) again by registering the `PickledObject` field.
- Worker: Added `--detach` option as an alias to `--daemon`, and it’s the term used in the documentation from now on.
- Make sure the pool and periodic task worker thread is terminated properly at exit (so `Control-c` works again).
- Now depends on `python-daemon`.
- Removed dependency to `simplejson`
- Cache Backend: Re-establishes connection for every task process if the Django cache backend is `python-memcached/libmemcached`.
- Tyrant Backend: Now re-establishes the connection for every task executed.

0.3.3

release-date  2009-06-08 01:07 p.m. CET
release-by   Ask Solem

- The `PeriodicWorkController` now sleeps for 1 second between checking for periodic tasks to execute.
0.3.2

**release-date** 2009-06-08 01:07 p.m. CET

**release-by** Ask Solem

- worker: Added option --discard: Discard (delete!) all waiting messages in the queue.
- Worker: The --wakeup-after option wasn’t handled as a float.

0.3.1

**release-date** 2009-06-08 01:07 p.m. CET

**release-by** Ask Solem

- The `PeriodicTask` worker is now running in its own thread instead of blocking the `TaskController` loop.
- Default `QUEUE_WAKEUP_AFTER` has been lowered to 0.1 (was 0.3)

0.3.0

**release-date** 2009-06-08 12:41 p.m. CET

**release-by** Ask Solem

**Warning:** This is a development version, for the stable release, please see versions 0.2.x.

VERY IMPORTANT: Pickle is now the encoder used for serializing task arguments, so be sure to flush your task queue before you upgrade.

- **IMPORTANT** `TaskSet.run()` now returns a `celery.result.TaskSetResult` instance, which lets you inspect the status and return values of a taskset as it was a single entity.
- **IMPORTANT** Celery now depends on carrot >= 0.4.1.
- The Celery daemon now sends task errors to the registered admin emails. To turn off this feature, set `SEND_CELERY_TASK_ERROR_EMAILS` to `False` in your `settings.py`. Thanks to Grégoire Cachet.
- You can now run the Celery daemon by using `manage.py`:

```
$ python manage.py celeryd
```

Thanks to Grégoire Cachet.

- Added support for message priorities, topic exchanges, custom routing keys for tasks. This means we’ve introduced `celery.task.apply_async`, a new way of executing tasks.

You can use `celery.task.delay` and `celery.Task.delay` like usual, but if you want greater control over the message sent, you want `celery.task.apply_async` and `celery.Task.apply_async`.

This also means the AMQP configuration has changed. Some settings has been renamed, while others are new:

- `CELERY_AMQP_EXCHANGE`
- `CELERY_AMQP PUBLISHER_ROUTING_KEY`
- `CELERY_AMQP_CONSUMER_ROUTING_KEY`
- `CELERY_AMQP_CONSUMER_QUEUE`
• **Task errors** are now logged using log level `ERROR` instead of `INFO`, and stack-traces are dumped. Thanks to Grégoire Cachet.

• Make every new worker process re-establish it’s Django DB connection, this solving the “MySQL connection died?” exceptions. Thanks to Vitaly Babiy and Jirka Vejrazka.

• **IMPORTANT** Now using pickle to encode task arguments. This means you now can pass complex Python objects to tasks as arguments.

• Removed dependency to `yadayada`.

• Added a FAQ, see `docs/faq.rst`.

• Now converts any Unicode keys in `kwargs` to regular strings. Thanks Vitaly Babiy.

• Renamed the `TaskDaemon` to `WorkController`.

• `celery.datastructures.TaskProcessQueue` is now renamed to `celery.pool.TaskPool`.

• The pool algorithm has been refactored for greater performance and stability.

### 0.2.0

**release-date** 2009-05-20 05:14 p.m. CET  
**release-by** Ask Solem  

• Final release of 0.2.0  

• Compatible with carrot version 0.4.0.  

• Fixes some syntax errors related to fetching results from the database backend.

### 0.2.0-pre3

**release-date** 2009-05-20 05:14 p.m. CET  
**release-by** Ask Solem  

• *Internal release.* Improved handling of unpickleable exceptions, `get_result` now tries to recreate something looking like the original exception.

### 0.2.0-pre2

**release-date** 2009-05-20 01:56 p.m. CET  
**release-by** Ask Solem  

• Now handles unpickleable exceptions (like the dynamically generated subclasses of `django.core.exception.MultipleObjectsReturned`).
0.2.0-pre1

**release-date** 2009-05-20 12:33 p.m. CET

**release-by** Ask Solem

- It’s getting quite stable, with a lot of new features, so bump version to 0.2. This is a pre-release.
- `celery.task.mark_as_read()` and `celery.task.mark_as_failure()` has been removed. Use `celery.backends.default_backend.mark_as_read()`, and `celery.backends.default_backend.mark_as_failure()` instead.

0.1.15

**release-date** 2009-05-19 04:13 p.m. CET

**release-by** Ask Solem

- The Celery daemon was leaking AMQP connections, this should be fixed, if you have any problems with too many files open (like `emfile` errors in `rabbit.log`, please contact us!

0.1.14

**release-date** 2009-05-19 01:08 p.m. CET

**release-by** Ask Solem

- Fixed a syntax error in the `TaskSet` class (no such variable `TimeOutError`).

0.1.13

**release-date** 2009-05-18 04:38 p.m. CET

**release-by** Ask Solem

- Forgot to add `yadayada` to install requirements.
- Now deletes all expired task results, not just those marked as done.
- Able to load the Tokyo Tyrant backend class without django configuration, can specify tyrant settings directly in the class constructor.
- Improved API documentation
- Now using the Sphinx documentation system, you can build the html documentation by doing:

```bash
$ cd docs
$ make html
```

and the result will be in `docs/_build/html`.

0.1.12

**release-date** 2009-05-18 04:38 p.m. CET

**release-by** Ask Solem
• *delay_task()* etc. now returns *celery.taskAsyncResult* object, which lets you check the result and any failure that might’ve happened. It kind of works like the *multiprocessingAsyncResult* class returned by *multiprocessing.Pool.map_async*.

• Added *dmap()* and *dmap_async()*. This works like the *multiprocessing.Pool* versions except they’re tasks distributed to the Celery server. Example:

```python
>>> from celery.task import dmap
>>> import operator
>>> dmap(operator.add, [[2, 2], [4, 4], [8, 8]])
>>> [4, 8, 16]

>>> from celery.task import dmap_async
>>> import operator
>>> result = dmap_async(operator.add, [[2, 2], [4, 4], [8, 8]])
>>> result.ready()
False
>>> time.sleep(1)
>>> result.ready()
True
>>> result.result
[4, 8, 16]
```

• Refactored the task meta-data cache and database backends, and added a new backend for Tokyo Tyrant. You can set the backend in your django settings file.

Example:

```ini
CELERY_RESULT_BACKEND = 'database'; # Uses the database
CELERY_RESULT_BACKEND = 'cache'; # Uses the django cache framework
CELERY_RESULT_BACKEND = 'tyrant'; # Uses Tokyo Tyrant
TT_HOST = 'localhost'; # Hostname for the Tokyo Tyrant server.
TT_PORT = 6657; # Port of the Tokyo Tyrant server.
```

0.1.11

**release-date** 2009-05-12 02:08 p.m. CET

**release-by** Ask Solem

• The logging system was leaking file descriptors, resulting in servers stopping with the EMFILES (too many open files) error (fixed).

0.1.10

**release-date** 2009-05-11 12:46 p.m. CET

**release-by** Ask Solem

• Tasks now supports both positional arguments and keyword arguments.

• Requires carrot 0.3.8.

• The daemon now tries to reconnect if the connection is lost.

0.1.8

**release-date** 2009-05-07 12:27 p.m. CET
release-by  Ask Solem
• Better test coverage
• More documentation
• The worker doesn’t emit *Queue is empty* message if *settings.CELERYD_EMPTY_MSG_EMIT_EVERY* is 0.

### 0.1.7

release-date  2009-04-30 01:50 p.m. CET
release-by  Ask Solem
• Added some unit tests
• Can now use the database for task meta-data (like if the task has been executed or not). Set *settings.CELERY_TASK_META*
• Can now run *python setup.py test* to run the unit tests from within the *tests* project.
• Can set the AMQP exchange/routing key/queue using *settings.CELERY_AMQP_EXCHANGE*, *settings.CELERY_AMQP_ROUTING_KEY*, and *settings.CELERY_AMQP_CONSUMER_QUEUE*.

### 0.1.6

release-date  2009-04-28 02:13 p.m. CET
release-by  Ask Solem
• Introducing *TaskSet*. A set of subtasks is executed and you can find out how many, or if all them, are done (excellent for progress bars and such)
• Now catches all exceptions when running *Task.__call__*, so the daemon doesn’t die. This doesn’t happen for pure functions yet, only *Task* classes.
• *autodiscover()* now works with zipped eggs.
• Worker: Now adds current working directory to *sys.path* for convenience.
• The *run_every* attribute of *PeriodicTask* classes can now be a *datetime.timedelta()* object.
• Worker: You can now set the *DJANGO_PROJECT_DIR* variable for the worker and it will add that to *sys.path* for easy launching.
• Can now check if a task has been executed or not via HTTP.
• You can do this by including the Celery *urls.py* into your project,

```python
>>> url(r'^celery/$', include('celery.urls'))
```
then visiting the following URL:

```
http://mysite/celery/$task_id/done/
```
this will return a JSON dictionary, for example:

```json
{"task": {"id": "TASK_ID", "executed": true}}
```
• *delay_task* now returns string id, not *uuid.UUID* instance.
• Now has *PeriodicTasks*, to have *cron* like functionality.

3.13. History
- Project changed name from crunchy to celery. The details of the name change request is in docs/name_change_request.txt.

0.1.0

release-date 2009-04-24 11:28 a.m. CET
release-by Ask Solem

- Initial release

Sphinx started sucking by removing images from _static, so we need to add them here into actual content to ensure they are included :-(

3.14 Glossary

ack Short for acknowledged.

acknowledged Workers acknowledge messages to signify that a message has been handled. Failing to acknowledge a message will cause the message to be redelivered. Exactly when a transaction is considered a failure varies by transport. In AMQP the transaction fails when the connection/channel is closed (or lost), but in Redis/SQS the transaction times out after a configurable amount of time (the visibility_timeout).

apply Originally a synonym to call but used to signify that a function is executed by the current process.

billiard Fork of the Python multiprocessing library containing improvements required by Celery.

calling Sends a task message so that the task function is executed by a worker.

cipater Celery release 3.1 named after song by Autechre (http://www.youtube.com/watch?v=OHsaqUr_33Y)

context The context of a task contains information like the id of the task, its arguments and what queue it was delivered to. It can be accessed as the tasks request attribute. See Task Request

early ack Short for early acknowledgment

early acknowledgment Task is acknowledged just-in-time before being executed, meaning the task won’t be redelivered to another worker if the machine loses power, or the worker instance is abruptly killed, mid-execution.

Configured using task_acks_late.

ETA “Estimated Time of Arrival”, in Celery and Google Task Queue, etc., used as the term for a delayed message that should not be processed until the specified ETA time. See ETA and Countdown.

executing Workers execute task requests.

idempotent Idempotence is a mathematical property that describes a function that can be called multiple times without changing the result. Practically it means that a function can be repeated many times without unintended effects, but not necessarily side-effect free in the pure sense (compare to nullipotent).

Further reading: https://en.wikipedia.org/wiki/Idempotent
**kombu**  Python messaging library used by Celery to send and receive messages.

**late ack**  Short for *late acknowledgment*

**late acknowledgment**  Task is *acknowledged* after execution (both if successful, or if the task is raising an error), which means the task will be redelivered to another worker in the event of the machine losing power, or the worker instance being killed mid-execution.

Configured using `task_acks_late`.

**nullipotent**  describes a function that’ll have the same effect, and give the same result, even if called zero or multiple times (side-effect free). A stronger version of *idempotent*.

**pidbox**  A process mailbox, used to implement remote control commands.

**prefetch count**  Maximum number of unacknowledged messages a consumer can hold and if exceeded the transport shouldn’t deliver any more messages to that consumer. See *Prefetch Limits*.

**prefetch multiplier**  The `prefetch count` is configured by using the `worker_prefetch_multiplier` setting, which is multiplied by the number of pool slots (threads/processes/greenthreads).

**reentrant**  describes a function that can be interrupted in the middle of execution (e.g., by hardware interrupt or signal), and then safely called again later. Reentrancy isn’t the same as *idempotence* as the return value doesn’t have to be the same given the same inputs, and a reentrant function may have side effects as long as it can be interrupted; An idempotent function is always reentrant, but the reverse may not be true.

**request**  Task messages are converted to *requests* within the worker. The request information is also available as the task’s `context` (the `task.request` attribute).
